Keywords: Lean 4; formal verification; domain theory; continuous lattices; neighbourhood systems; information systems; Scott topology

Abstract

This document is a machine-checked Lean 4 formalization of Dana Scott's papers on domain theory: continuous lattices (1972), datatypes as lattices (1976), neighbourhood systems (1980), and information systems (1982), together with bridge theorems relating the lattice, neighbourhood, and information systems presentations. Beyond the lattice and retract development, the 1976 material covers Scott's computability apparatus for the universal domain $\mathbf{P}\omega$ (the language LAMBDA, enumeration and recursion, definability, and enumeration degrees as combinatory subalgebras) and a descriptive-set style classification of subsets of $\mathbf{P}\omega$ (open, closed, $\mathfrak{G}_\delta$, Boolean, and related classes characterized as fibres of continuous maps). The library is registered with Palomar as PALOMAR-2026-11-12-000010 (version 1).

Contents

1 Introduction **25**

2 Continuous Lattices (1972) ✓ **26**
2.1 Introduction ✓ . . . 27
2.2 Injective spaces ✓ . . . 28
2.2.1 Definition 1.1: Injective Space ✓ . . . 29
2.2.2 Proposition 1.2 ✓ . . . 30
2.2.3 Proposition 1.3 ✓ . . . 30
2.2.4 Powers of $\mathbb{O}$ are injective ✓ . . . 31
2.2.5 Proposition 1.4 ✓ . . . 32
2.2.6 Proposition 1.5 ✓ . . . 32
2.2.7 RetractSubspace ✓ . . . 33
2.2.8 Corollary 1.6 ✓ . . . 34
2.2.9 Corollary 1.7 ✓ . . . 34
2.2.10 Absolute retracts ✓ . . . 35
2.3 Continuous lattices ✓ . . . 36
2.3.1 Specialization order ✓ . . . 37
2.3.2 Way-below relation ✓ . . . 47
2.3.3 Continuous lattice ✓ . . . 52
2.3.4 Scott maps ✓ . . . 65
2.3.5 Proposition 2.8 ✓ . . . 73
2.3.6 Proposition 2.9 ✓ . . . 74
2.3.7 Proposition 2.10 ✓ . . . 76
2.3.8 Proposition 2.11 ✓ . . . 77
2.3.9 Proof of 2.9 ✓ . . . 78
2.3.10 Continuous lattice retraction ✓ . . . 79
2.3.11 Converse retraction ✓ . . . 81
2.3.12 Continuous lattice projection ✓ . . . 83
2.3.13 Converse projection ✓ . . . 88
2.3.14 Proof of 2.10 ✓ . . . 88
2.3.15 Proof of 2.11 ✓ . . . 90
2.4 Function spaces ✓ . . . 100
2.4.1 Induced pi topology on $C(X, Y)$ ✓ . . . 100
2.4.2 Definition 3.1: Function space ✓ . . . 101
2.4.3 Elements of $[D \to D']$ ✓ . . . 104
2.4.4 Step function (pointwise) ✓ . . . 114
2.4.5 Step map $\overrightarrow{e}[e, e']$ ✓ . . . 115
2.4.6 Proposition 3.2 ✓ . . . 117
2.4.7 Product topology on $[D \to D']$ ✓ . . . 118
2.4.8 Theorem 3.3 ✓ . . . 122
2.4.9 Corollary 3.4 ✓ . . . 123
2.4.10 Scott functional abstraction ✓ . . . 125
2.4.11 Proposition 3.5 ✓ . . . 128

2.4.12 Retractions and extensions ✓ . . . 129
2.4.13 Definition 3.6 ✓ . . . 131
2.4.14 Function-space retraction and projection ✓ . . . 132
2.4.15 Proposition 3.7 ✓ . . . 133
2.4.16 Scott subspace extension ✓ . . . 134
2.4.17 Proposition 3.8 ✓ . . . 137
2.4.18 Lemma 3.9 ✓ . . . 139
2.4.19 Proposition 3.10 ✓ . . . 141
2.4.20 Definition 3.11: Projection space ✓ . . . 145
2.4.21 Proposition 3.12 ✓ . . . 148
2.4.22 Proposition 3.13 ✓ . . . 149
2.4.23 Proposition 3.14 ✓ . . . 151
2.5 Inverse limits ✓ . . . 152
2.5.1 Compatibility ✓ . . . 152
2.5.2 InverseLimit ✓ . . . 153
2.5.3 Projections from the limit ✓ . . . 154
2.5.4 The mediating map ✓ . . . 154
2.5.5 Special inverse systems ✓ . . . 156
2.5.6 Projections along the tower ✓ . . . 156
2.5.7 Tower step adjunction ✓ . . . 159
2.5.8 Embeddings along the tower ✓ . . . 160
2.5.9 Coordinates of an embedding ✓ . . . 162
2.5.10 Embeddings into the limit ✓ . . . 165
2.5.11 Order on the inverse limit ✓ . . . 166
2.5.12 Strict order on the inverse limit ✓ . . . 167
2.5.13 The limit lattice ✓ . . . 169
2.5.14 Topology of the inverse limit ✓ . . . 180
2.5.15 Proposition 4.1 ✓ . . . 184
2.5.16 Proposition 4.2 ✓ . . . 185
2.5.17 Corollary 4.3 ✓ . . . 187
2.5.18 The function space tower . . . 189
2.5.19 The functorial form ✓ . . . 216
2.5.20 Application ✓ . . . 216
2.5.21 Two projections ✓ . . . 217
2.5.22 Embedding every space ✓ . . . 217
2.5.23 Other functors ✓ . . . 218
2.5.24 Subspaces of a limit ✓ . . . 219
2.6 Correction ✓ . . . 219

3 Datatypes as Lattices (1976) ✓ 221
3.1 Introduction . . . 221
3.1.1 Domain $\mathbf{P}\omega$ ✓ . . . 222
3.1.2 Multiple-valued integers ✓ . . . 223
3.2 Continuous functions . . . 224
3.2.1 Introduction ✓ . . . 224
3.2.2 Finite subsets and the enumeration e_n ✓ . . . 225

3.2.3 Cantor pairing of integer pairs (n, m) ✓ . . . 236
3.2.4 Basic open sets and continuity on $\mathbf{P}\omega$ ✓ . . . 240
3.2.5 Graphs of continuous functions ✓ . . . 249
3.2.6 Fixed points and least fixed points . . . 253
3.2.7 Extension and embedding of continuous maps . . . 259
3.3 Computability and definability . . . 268
3.3.1 Minimal and maximal extension ✓ . . . 269
3.3.2 Meaning ✓ . . . 270
3.3.3 The language LAMBDA ✓ . . . 271
3.3.4 Term avoidance (α) ✓ . . . 277
3.3.5 Theorem 2.1 — the continuity theorem ✓ . . . 278
3.3.6 Theorem 2.2 — the conversion theorem ✓ . . . 279
3.3.7 Theorem 2.3 — the reduction theorem ✓ . . . 281
3.3.8 Theorem 2.4 — the combinator theorem ✓ . . . 282
3.3.9 The combinator Y ✓ . . . 283
3.3.10 Theorem 2.5 — the first recursion theorem ✓ . . . 285
3.3.11 The graph model ✓ . . . 286
3.3.12 Sequences ✓ . . . 288
3.3.13 Distributive functions ✓ . . . 295
3.3.14 The definability theorem ✓ . . . 303
3.3.15 A law of Y ✓ . . . 321
3.4 Enumeration and degrees . . . 323
3.4.1 Introduction ✓ . . . 323
3.4.2 G-combinator tools ✓ . . . 325
3.4.3 Theorem 3.1 ✓ . . . 335
3.4.4 Application ✓ . . . 337
3.4.5 Unpairing ✓ . . . 339
3.4.6 Numerals ✓ . . . 341
3.4.7 Val rank ✓ . . . 342
3.4.8 Theorem 3.2 ✓ . . . 343
3.4.9 Recursion codes ✓ . . . 344
3.4.10 Plotkin helpers ✓ . . . 345
3.4.11 Theorem 3.3 ✓ . . . 347
3.4.12 Theorem 3.4 ✓ . . . 349
3.4.13 Theorem 3.5 ✓ . . . 351
3.4.14 Theorem 3.6 ✓ . . . 356
3.4.15 Theorem 3.7 ✓ . . . 359
3.5 Retracts and data types . . . 362
3.5.1 Introduction ✓ . . . 362
3.5.2 Graph lemmas ✓ . . . 364
3.5.3 Predecessor set ✓ . . . 364
3.5.4 Fixpoints ✓ . . . 365
3.5.5 Directed fixpoints ✓ . . . 366
3.5.6 Definition (retract) ✓ . . . 369
3.5.7 Theorem 4.1 ✓ . . . 377

3.5.8 u is in the range of retract a ✓ . . . 379
3.5.9 Definition (ordering) ✓ . . . 379
3.5.10 Open-set retract ✓ . . . 380
3.5.11 Theorem 4.2 ✓ . . . 380
3.5.12 Theorem 4.3 ✓ . . . 382
3.5.13 C combinators ✓ . . . 384
3.5.14 Pair mediation ✓ . . . 387
3.5.15 Theorem 4.4 ✓ . . . 387
3.5.16 Theorem 4.5 ✓ . . . 392
3.5.17 Expression interpreter ✓ . . . 395
3.5.18 Theorem 4.6 ✓ . . . 416
3.6 Closure operations and algebraic lattices . . . 421
3.6.1 Introduction ✓ . . . 421
3.6.2 Isolated ✓ . . . 422
3.6.3 Bottom ✓ . . . 422
3.6.4 Square pair ✓ . . . 423
3.6.5 Predecessor identities ✓ . . . 424
3.6.6 Directed finite cover ✓ . . . 425
3.6.7 Is compact ✓ . . . 425
3.6.8 Continuous basis ✓ . . . 426
3.6.9 Countably algebraic ✓ . . . 426
3.6.10 Representation ✓ . . . 429
3.6.11 Closure operation ✓ . . . 430
3.6.12 Theorem 5.1 — the algebraic lattice theorem ✓ . . . 432
3.6.13 Theorem 5.2 — the representation theorem ✓ . . . 432
3.6.14 Theorem 5.3 — the function space theorem ✓ . . . 434
3.6.15 Theorem 5.4 — the product and sum theorem ✓ . . . 435
3.6.16 Theorem 5.5 — the universe theorem ✓ . . . 436
3.6.17 Theorem 5.6 — the limit theorem ✓ . . . 437
3.7 Subsets and their classification . . . 439
3.7.1 Introduction ✓ . . . 439
3.7.2 Scott classes ✓ . . . 440
3.7.3 Characteristic maps ✓ . . . 442
3.7.4 Odd-even packing ✓ . . . 446
3.7.5 Pair indexing ✓ . . . 449
3.7.6 F∩Gδ packing ✓ . . . 451
3.7.7 Three-valued ✓ . . . 453
3.7.8 Boolean membership ✓ . . . 461
3.7.9 Theorem 6.1 — the G theorem ✓ . . . 464
3.7.10 Theorem 6.2 — the F theorem ✓ . . . 465
3.7.11 Theorem 6.3 — the Gδ theorem ✓ . . . 467
3.7.12 Theorem 6.4 — the F∩G theorem ✓ . . . 468
3.7.13 Theorem 6.5 — the F∩Gδ theorem ✓ . . . 471
3.7.14 Theorem 6.6 — the B theorem ✓ . . . 473
3.7.15 Theorem 6.7 — the Bδ theorem ✓ . . . 475

3.8 Total functions and functionality . . . 484
3.8.1 Introduction ✓ . . . 484
3.8.2 Pair elements ✓ . . . 485
3.8.3 Restricted equivalence relations ✓ . . . 486
3.8.4 Theorem 7.1 ✓ . . . 491
3.8.5 Theorem 7.2 ✓ . . . 492
3.8.6 Theorem 7.3 ✓ . . . 497
3.8.7 Theorem 7.4 ✓ . . . 504
3.9 Acknowledgements and references . . . 516

4 Neighborhood Systems (1980) ✓ 519
4.1 Introduction . . . 519
4.2 Domains given by neighbourhoods . . . 521
4.2.1 Introduction . . . 522
4.2.2 Definition 1.1 — neighbourhood system . . . 522
4.2.3 Finite intersections . . . 523
4.2.4 Empty intersection is delta . . . 526
4.2.5 Recursive finite intersection . . . 526
4.2.6 Element order and sequence limits . . . 527
4.2.7 Total elements . . . 528
4.2.8 Two-token neighbourhoods . . . 528
4.2.9 Example 1.2 — two-token domain . . . 531
4.2.10 Three-token neighbourhoods . . . 533
4.2.11 Example 1.3 — three-step chain . . . 535
4.2.12 Binary-tree tokens . . . 536
4.2.13 More neighbourhood-system facts . . . 540
4.2.14 Three-set consistency counterexample . . . 554
4.2.15 Ideal neighbourhoods . . . 556
4.2.16 Final-segment orders . . . 559
4.2.17 Greedy enumeration . . . 562
4.2.18 Positive difference systems . . . 566
4.2.19 Rational intervals . . . 568
4.2.20 Cofinite neighbourhoods . . . 570
4.2.21 Flat and stem systems . . . 572
4.2.22 Finite nonempty neighbourhoods . . . 576
4.2.23 Branch sequences . . . 577
4.2.24 Final-segment naturals . . . 579
4.2.25 Example 1.4 — finite binary tree . . . 581
4.2.26 Are two neighbourhoods nested or disjoint? . . . 583
4.2.27 Four-token powerset . . . 584
4.2.28 Example 1.5 — all nonempty subsets . . . 585
4.2.29 Consistent iff nonempty . . . 585
4.2.30 Equivalent sequences with same limit . . . 587
4.2.31 Definition 1.6 — ideal elements . . . 588
4.2.32 Definition 1.7 — principal filter . . . 589
4.2.33 Inclusion reversing principals . . . 590

4.2.34 Principals are one-one . . . 591
4.2.35 Union of principal filters . . . 592
4.2.36 Definition 1.8 — approximation and totality . . . 593
4.2.37 Bottom element . . . 593
4.2.38 Bottom is least . . . 594
4.2.39 Finite filters are principal . . . 594
4.2.40 The cone of finite bit strings . . . 596
4.2.41 Examples 1.2–1.5 (Revisited) — infinite binary neighbourhoods . . . 597
4.2.42 Prefix order . . . 600
4.2.43 Union of finite approximations . . . 602
4.2.44 Definition 1.9 — isomorphic domains . . . 603
4.2.45 Brackets . . . 604
4.2.46 Token system . . . 606
4.2.47 Theorem 1.10 — basic open neighbourhoods . . . 608
4.2.48 Countable intersection of ideal elements . . . 610
4.2.49 Directed union of ideal elements . . . 611
4.2.50 Theorem 1.11 — intersections and directed unions . . . 613
4.2.51 Lecture I exercises . . . 617
4.3 Mappings between domains . . . 632
4.3.1 Introduction . . . 633
4.3.2 Definition 2.1 — approximable mapping . . . 633
4.3.3 Proposition 2.2 — elementwise action . . . 636
4.3.4 Two-token ideal elements . . . 638
4.3.5 Parity scan into truth . . . 642
4.3.6 Example 2.3 — parity of leading zeros . . . 645
4.3.7 Erase a run of ones . . . 647
4.3.8 Example 2.4 — erase a run of ones . . . 650
4.3.9 Identity approximable map . . . 651
4.3.10 Neighborhood systems as category objects . . . 654
4.3.11 Theorem 2.5 — category of approximable maps . . . 655
4.3.12 Proposition 2.6 — identity and composition . . . 657
4.3.13 Order isomorphism as approximable map . . . 657
4.3.14 Theorem 2.7 — isomorphisms are approximable . . . 660
4.3.15 Monotone on principals as approximable map . . . 662
4.3.16 Exercise 2.8 — determined by finite elements . . . 663
4.3.17 Exercise 2.9 — directed union formula . . . 664
4.3.18 Pointwise intersection of approximable maps . . . 665
4.3.19 Exercise 2.10 — intersection of two maps . . . 666
4.3.20 Indexed directed supremum of ideal elements . . . 667
4.3.21 Exercise 2.11 — directed unions of elements . . . 668
4.3.22 Directed supremum of approximable maps . . . 669
4.3.23 Exercise 2.12 — directed unions of maps . . . 671
4.3.24 Continuous maps as approximable . . . 671
4.3.25 Exercise 2.13 — approximable means continuous . . . 675
4.3.26 Neighbourhood correspondence of an order isomorphism . . . 676

4.3.27 Exercise 2.14 — isomorphisms of neighbourhoods . . . 678
4.3.28 One-token Sierpiński neighbourhood system . . . 679
4.3.29 Exercise 2.15 — opens classified by maps . . . 684
4.3.30 Prefixing map and parity equations . . . 684
4.3.31 Exercise 2.16 — prefixing is approximable . . . 687
4.3.32 Uniqueness of the erase-ones map . . . 688
4.3.33 Exercise 2.17 — erase-ones map . . . 690
4.3.34 Insert-zero map and left inverse . . . 691
4.3.35 Exercise 2.18 — doubling binary digits . . . 695
4.3.36 Approximable maps of two arguments . . . 696
4.3.37 Exercise 2.19 — maps of two arguments . . . 700
4.3.38 Powerset neighbourhood system . . . 701
4.3.39 Exercise 2.20 — powerset of the integers . . . 708
4.3.40 Finite and infinite sequence neighbourhood system . . . 708
4.3.41 Exercise 2.21 — finite and infinite sequences . . . 714
4.3.42 Token neighbourhood system of a closed family . . . 715
4.3.43 Exercise 2.22 — domains from closure properties . . . 722
4.4 Domain constructs . . . 723
4.4.1 Introduction . . . 724
4.4.2 Definition 3.1 — product of systems . . . 724
4.4.3 Product element order isomorphism . . . 730
4.4.4 Proposition 3.2 — elements of a product . . . 732
4.4.5 Definition 3.3 — projection mappings . . . 733
4.4.6 Proposition 3.4 — pairing and projections . . . 738
4.4.7 Theorem 3.5 — separate approximability . . . 739
4.4.8 Constant approximable map . . . 740
4.4.9 Lemma 3.6 — constant functions . . . 741
4.4.10 Elementwise substitution . . . 743
4.4.11 Proposition 3.7 — closure under substitution . . . 743
4.4.12 Step neighbourhoods of maps . . . 745
4.4.13 Intersection of range neighbourhoods . . . 747
4.4.14 Least map of a step list . . . 748
4.4.15 Definition 3.8 — function space . . . 751
4.4.16 Proposition 3.9 — consistent step neighbourhoods . . . 753
4.4.17 Function-space element isomorphism . . . 755
4.4.18 Theorem 3.10 — elements are mappings . . . 758
4.4.19 Evaluation combinator . . . 759
4.4.20 Theorem 3.11 — evaluation combinator . . . 761
4.4.21 Currying . . . 762
4.4.22 Theorem 3.12 — currying . . . 767
4.4.23 Pointwise supremum of maps . . . 769
4.4.24 Theorem 3.13 — pointwise order of maps . . . 773
4.4.25 Diagonal map . . . 774
4.4.26 Exercise 3.14 — tagged product of tokens . . . 775
4.4.27 Product isomorphisms . . . 776

4.4.28 Exercise 3.15 — product isomorphisms . . . 779
4.4.29 Infinite sequence system . . . 780
4.4.30 Exercise 3.16 — infinite sequences of elements . . . 788
4.4.31 Embedding binary sequences . . . 789
4.4.32 Exercise 3.17 — embedding binary sequences . . . 794
4.4.33 Sum system . . . 795
4.4.34 Exercise 3.18 — separated sum . . . 807
4.4.35 Induced maps . . . 807
4.4.36 Exercise 3.19 — induced maps on constructs . . . 811
4.4.37 Product functor . . . 813
4.4.38 Exercise 3.20 — sum and product functors . . . 814
4.4.39 Identity of step neighbourhoods . . . 815
4.4.40 Exercise 3.21 — identity of step neighbourhoods . . . 818
4.4.41 Composition combinator . . . 819
4.4.42 Exercise 3.22 — composition combinator . . . 820
4.4.43 Cartesian closed category . . . 822
4.4.44 Exercise 3.23 — cartesian closed category . . . 823
4.4.45 Function-space isomorphisms . . . 823
4.4.46 Exercise 3.24 — function-space isomorphisms . . . 830
4.4.47 Opens form a domain . . . 832
4.4.48 Exercise 3.25 — opens form a domain . . . 835
4.4.49 Conditional combinator . . . 835
4.4.50 Exercise 3.26 — conditional combinator . . . 848
4.4.51 Function space via closure . . . 850
4.4.52 Exercise 3.27 — function space via closure . . . 853
4.4.53 Minimal step function . . . 854
4.4.54 Exercise 3.28 — minimal step function . . . 856
4.5 Fixed points and recursion . . . 857
4.5.1 Introduction . . . 858
4.5.2 Least fixed-point element . . . 859
4.5.3 Theorem 4.1 — least fixed point . . . 862
4.5.4 Fix combinator . . . 863
4.5.5 Theorem 4.2 — fix combinator . . . 868
4.5.6 Number domain . . . 870
4.5.7 Example 4.3 — partial functions on integers . . . 875
4.5.8 Sequence domain . . . 879
4.5.9 Example 4.4 — sequence domain . . . 883
4.5.10 Definition 4.5 — Peano axioms . . . 886
4.5.11 Theorem 4.6 — Peano models isomorphic . . . 888
4.5.12 Fixed point above a seed . . . 890
4.5.13 Exercise 4.7 — fixed point above a seed . . . 893
4.5.14 Iterate-chain supremum . . . 893
4.5.15 Fixed-point induction . . . 895
4.5.16 Exercise 4.8 — fixed-point induction . . . 896
4.5.17 Psi operator . . . 897

4.5.18 Exercise 4.9 — fix as a fixed point . . . 899
4.5.19 Domain above an element . . . 900
4.5.20 Exercise 4.10 — domain above an element . . . 906
4.5.21 Uniform fix uniqueness . . . 906
4.5.22 Exercise 4.11 — characterizing the fix combinator . . . 910
4.5.23 No greatest fixed point . . . 911
4.5.24 Exercise 4.12 — no greatest fixed point . . . 913
4.5.25 Monotone fixed-point operator . . . 914
4.5.26 Exercise 4.13 — avoiding the natural numbers . . . 916
4.5.27 Greatest powerset fixed point . . . 917
4.5.28 Exercise 4.14 — greatest powerset fixed point . . . 919
4.5.29 Maximal fixed points . . . 919
4.5.30 Exercise 4.15 — maximal fixed points . . . 921
4.5.31 Optimal fixed point . . . 921
4.5.32 Exercise 4.16 — optimal fixed point . . . 923
4.5.33 Generated submonoid . . . 924
4.5.34 Exercise 4.17 — generated submonoid . . . 926
4.5.35 Number-domain checks . . . 927
4.5.36 Exercise 4.18 — checking the number domain . . . 929
4.5.37 Peano structure on sequences . . . 929
4.5.38 Exercise 4.19 — Peano axioms for sequences . . . 935
4.5.39 Fix of a composite . . . 936
4.5.40 Exercise 4.20 — fix of a composite . . . 937
4.5.41 Order as a fixed point . . . 938
4.5.42 Exercise 4.21 — order as a fixed point . . . 941
4.5.43 Inductive Peano submodel . . . 942
4.5.44 Exercise 4.22 — inductive subset of a model . . . 944
4.5.45 Unique fixed point . . . 945
4.5.46 Exercise 4.23 — commuting with the iterates . . . 946
4.5.47 Schroeder-Bernstein . . . 947
4.5.48 Exercise 4.24 — Schroeder-Bernstein theorem . . . 949
4.5.49 Unary sequence domain . . . 950
4.5.50 Exercise 4.25 — unary sequence domain . . . 954
4.6 Typed λ-calculus . . . 955
4.6.1 Introduction . . . 955
4.6.2 Theorem 5.1 — terms denote approximable maps . . . 959
4.6.3 Beta conversion . . . 961
4.6.4 Theorem 5.2 — beta conversion . . . 963
4.6.5 Paired fixed point . . . 965
4.6.6 Proposition 5.3 — simultaneous fixed points . . . 968
4.6.7 Parametric fixed point . . . 969
4.6.8 Proposition 5.4 — fixed point under a parameter . . . 972
4.6.9 Table 5.5 — table of combinators . . . 973
4.6.10 Number-domain recursion schemes . . . 979
4.6.11 Infinite-product stack combinators . . . 985

4.6.12 Number-stack argument encoding . . . 988
4.6.13 Partial-recursive scheme realizers . . . 995
4.6.14 Partial recursive λ-definability . . . 1001
4.6.15 Theorem 5.6 — partial recursive functions . . . 1006
4.6.16 Multi-argument λ-abstraction . . . 1008
4.6.17 Exercise 5.7 — currying the lambda notation . . . 1010
4.6.18 Combinatory completeness . . . 1011
4.6.19 Exercise 5.8 — combinatory completeness . . . 1014
4.6.20 Exercise 5.9 — common fixed points . . . 1015
4.6.21 Smash product . . . 1016
4.6.22 Exercise 5.10 — smash product . . . 1033
4.6.23 Diagonal and map stacks . . . 1034
4.6.24 Exercise 5.11 — stack combinators . . . 1037
4.6.25 While combinator . . . 1038
4.6.26 Exercise 5.12 — while combinator . . . 1040
4.6.27 Natural-number pairing . . . 1041
4.6.28 Exercise 5.13 — pairing function on numbers . . . 1044
4.6.29 Powerset isomorphisms . . . 1045
4.6.30 Exercise 5.13 — powerset isomorphisms . . . 1046
4.6.31 Set graphs . . . 1047
4.6.32 Exercise 5.14 — functions as graphs . . . 1050
4.6.33 Language star . . . 1051
4.6.34 Exercise 5.15 — star of a word . . . 1057
4.6.35 Sequence negation and merge . . . 1058
4.6.36 Exercise 5.16 — negation of sequences . . . 1078
4.7 Domain equations . . . 1079
4.7.1 Introduction . . . 1080
4.7.2 Indefinite product . . . 1081
4.7.3 Example 6.1 — indefinite product . . . 1090
4.7.4 seqEqB — B equation . . . 1095
4.7.5 seqEqA — A^n equation . . . 1104
4.7.6 seqEqC — C equation . . . 1115
4.7.7 seqEqRegular — regular trees . . . 1131
4.7.8 Example 6.2 — sequence domain equations . . . 1133
4.7.9 Endofunctor . . . 1135
4.7.10 Definition 6.3 — functor . . . 1136
4.7.11 T-algebra . . . 1137
4.7.12 Definition 6.4 — algebra for a functor . . . 1138
4.7.13 Initial algebra . . . 1139
4.7.14 Definition 6.5 — initial algebra . . . 1141
4.7.15 Initial iso . . . 1141
4.7.16 Proposition 6.6 — uniqueness of initial algebras . . . 1142
4.7.17 Lambek . . . 1143
4.7.18 Proposition 6.7 — functor preserves initiality . . . 1144
4.7.19 Continuous on maps . . . 1145

4.7.20 Definition 6.8 — continuity on maps . . . 1146
4.7.21 Initial homomorphism . . . 1147
4.7.22 Theorem 6.9 — homomorphism from initial algebra . . . 1151
4.7.23 Subdomain . . . 1152
4.7.24 Definition 6.10 — subdomain . . . 1153
4.7.25 Subsystem lattice . . . 1154
4.7.26 Proposition 6.11 — lattice of subsystems . . . 1159
4.7.27 Projection pair library . . . 1160
4.7.28 Proposition 6.12 — projection pair . . . 1162
4.7.29 Continuous on domains . . . 1163
4.7.30 Definition 6.13 — continuity on domains . . . 1164
4.7.31 Exists initial . . . 1165
4.7.32 Theorem 6.14 — existence of initial algebras . . . 1168
4.7.33 Proj pair subdomain . . . 1170
4.7.34 Lemma 6.15 — subdomains from projection pairs . . . 1174
4.7.35 Minimal initial . . . 1175
4.7.36 Theorem 6.16 — initial algebra is minimal . . . 1180
4.7.37 Lecture VI exercises . . . 1192
4.7.38 cAlgebra — C initial algebra . . . 1192
4.7.39 cAlgebraGen — Cn over A . . . 1203
4.7.40 Exercise 6.17 — algebras for sequence domains . . . 1233
4.7.41 iterProdInitial — D^∞ initial . . . 1234
4.7.42 Exercise 6.18 — infinite product as initial . . . 1244
4.7.43 sumProdTok — strict sum and product . . . 1244
4.7.44 Exercise 6.19 — strict sum and product . . . 1255
4.7.45 functorTokens — FExpr functor algebra . . . 1256
4.7.46 Exercise 6.20 — tokens of a functor . . . 1269
4.7.47 coalesceSmash — coalesced sum and smash . . . 1269
4.7.48 Exercise 6.21 — coalesced sum and smash . . . 1289
4.7.49 intExprDomains — integer equations . . . 1289
4.7.50 Exercise 6.22 — equations for the integers . . . 1308
4.7.51 exprDomain — syntactic Exp . . . 1308
4.7.52 Exercise 6.23 — syntactic expression domain . . . 1310
4.7.53 recDomainEq — simultaneous solutions . . . 1311
4.7.54 Exercise 6.24 — recursive domain equations . . . 1314
4.7.55 projPairLaws — projection pair laws . . . 1314
4.7.56 Exercise 6.25 — projection pair laws . . . 1316
4.7.57 liftDomain — lifting a domain . . . 1317
4.7.58 Exercise 6.26 — lifting a domain . . . 1332
4.7.59 embeddingCompare — which embeddings hold . . . 1332
4.7.60 Exercise 6.27 — which embeddings hold . . . 1349
4.7.61 finiteEmbedCancel — finite mutual embeddings . . . 1349
4.7.62 Exercise 6.28 — finite embeddings cancel . . . 1352
4.7.63 infSumProd — infinitary sum and product . . . 1352
4.7.64 Exercise 6.29 — infinitary sum and product . . . 1366

4.8 Computability in effectively given domains . . . 1367
4.8.1 Introduction . . . 1368
4.8.2 Recursive predicates . . . 1368
4.8.3 Computable presentation . . . 1439
4.8.4 Definition 7.1 — computable presentation . . . 1443
4.8.5 Computable map . . . 1444
4.8.6 Definition 7.2 — computable mapping . . . 1445
4.8.7 Computable maps form a category . . . 1447
4.8.8 Proposition 7.3 — computable maps form a category . . . 1448
4.8.9 Effective sum . . . 1449
4.8.10 Effective product . . . 1467
4.8.11 Theorem 7.4 — sum and product effective . . . 1471
4.8.12 Function-space presentation . . . 1474
4.8.13 Theorem 7.5 — function space effective . . . 1512
4.8.14 Computable fixpoint . . . 1515
4.8.15 Theorem 7.6 — fix is computable . . . 1517
4.8.16 Effectively given lists . . . 1518
4.8.17 List combinators . . . 1545
4.8.18 Proposition 7.7 — lists effectively given . . . 1551
4.8.19 Powerset neighbourhoods . . . 1552
4.8.20 Example 7.8 — powerset effectively given . . . 1555
4.8.21 Power domain . . . 1556
4.8.22 Definition 7.9 — power domain . . . 1558
4.8.23 Effective powerdomain . . . 1559
4.8.24 Proposition 7.10 — power domain effective . . . 1569
4.8.25 Finite powerdomain elements . . . 1570
4.8.26 Definition 7.11 — finite sets of elements . . . 1573
4.8.27 Finite-join approximation . . . 1574
4.8.28 V-shape counterexample . . . 1582
4.8.29 Proposition 7.12 — finite sets are approximable . . . 1585
4.8.30 Lecture VII exercises . . . 1588
4.8.31 Inclusion structures . . . 1588
4.8.32 Exercise 7.13 — axiomatic neighbourhood structure . . . 1596
4.8.33 Computable witnesses . . . 1597
4.8.34 Exercise 7.14 — primitive recursive witnesses . . . 1602
4.8.35 Scott presentation . . . 1603
4.8.36 Effective smash . . . 1606
4.8.37 Coalesced sum . . . 1620
4.8.38 Effective iterate . . . 1639
4.8.39 Exercise 7.15 — further constructs effective . . . 1646
4.8.40 Curry enumeration . . . 1646
4.8.41 Exercise 7.16 — curry as an enumeration . . . 1651
4.8.42 List recursion . . . 1652
4.8.43 Exercise 7.17 — recursion over lists . . . 1666
4.8.44 Effective isomorphism . . . 1667

4.8.45 Exercise 7.18 — effective isomorphism . . . 1678
4.8.46 Powerdomain functor . . . 1679
4.8.47 Exercise 7.19 — power domain functor . . . 1688
4.8.48 Powerdomain union . . . 1689
4.8.49 Exercise 7.20 — union on power domains . . . 1692
4.8.50 Pointwise application . . . 1693
4.8.51 Exercise 7.21 — distributing the power domain . . . 1697
4.8.52 Regular languages . . . 1698
4.8.53 Regular-language codes . . . 1736
4.8.54 Language presentation . . . 1775
4.8.55 Exercise 7.22 — domain of formal languages . . . 1799
4.8.56 Graph map . . . 1800
4.8.57 Exercise 7.23 — graph and fun computable . . . 1833
4.8.58 LUCID histories . . . 1834
4.8.59 Exercise 7.24 — LUCID history domain . . . 1878
4.9 Retracts of the universal domain . . . 1879
4.9.1 Introduction . . . 1880
4.9.2 Retraction . . . 1881
4.9.3 Definition 8.1 — retraction . . . 1883
4.9.4 Proposition 8.2 — retractions from subdomains . . . 1884
4.9.5 Projection . . . 1885
4.9.6 Definition 8.3 — projections . . . 1887
4.9.7 Fixed neighbourhood . . . 1887
4.9.8 Fix of O . . . 1895
4.9.9 Strict retraction . . . 1905
4.9.10 Smash retraction . . . 1909
4.9.11 Examples 8.4 — check, fade, and smash . . . 1915
4.9.12 Theorem 8.5 — finitary projection test . . . 1917
4.9.13 Sub . . . 1918
4.9.14 SubApprox . . . 1922
4.9.15 DprimeU . . . 1929
4.9.16 Theorem 8.6 — sub combinator . . . 1936
4.9.17 Presented intervals . . . 1938
4.9.18 Universal domain U . . . 1943
4.9.19 Split specification . . . 1947
4.9.20 Atoms of U . . . 1948
4.9.21 Y-sequence . . . 1956
4.9.22 Definition 8.7 — interval presentation of U . . . 1961
4.9.23 Fixed neighbourhood effective . . . 1963
4.9.24 U constructs . . . 1964
4.9.25 Theorem 8.8 — universality of U . . . 1965
4.9.26 Lam combinator . . . 1967
4.9.27 Sum combinator . . . 1968
4.9.28 Product combinator . . . 1974
4.9.29 Arrow combinator . . . 1976

4.9.30 Exponential map . . . 1978
4.9.31 Definition 8.9 — constructs on projections . . . 1979
4.9.32 Element iso of projection pair . . . 1982
4.9.33 Proposition 8.10 — constructs preserve projections . . . 1984
4.9.34 Lecture VIII exercises . . . 1985
4.9.35 Dedekind cut projection . . . 1985
4.9.36 Exercise 8.11 — retraction on intervals . . . 1997
4.9.37 Effective isomorphism U and V . . . 1997
4.9.38 Exercise 8.12 — integer presentation of U . . . 1998
4.9.39 Boolean-algebra filters . . . 1999
4.9.40 Generated-by filters . . . 2007
4.9.41 Exercise 8.13 — Boolean-algebra filters . . . 2008
4.9.42 Closure operator domain . . . 2008
4.9.43 Exercise 8.14 — closure operators . . . 2017
4.9.44 Finitely generated subsystems . . . 2017
4.9.45 Subsystem domain . . . 2026
4.9.46 Exercise 8.15 — domain of subsystems . . . 2033
4.9.47 Fixed-neighbourhood finitary order . . . 2033
4.9.48 Exercise 8.16 — order of projections . . . 2035
4.9.49 Embeddings into U . . . 2035
4.9.50 Embeddings into U (more) . . . 2038
4.9.51 Projection pairs . . . 2048
4.9.52 Exercise 8.17 — explicit embeddings into U . . . 2050
4.9.53 Projection combinators . . . 2051
4.9.54 Exercise 8.18 — missing proofs of 8.10 . . . 2051
4.9.55 Sum and product retracts . . . 2052
4.9.56 Exercise 8.19 — closure under sum and product . . . 2057
4.9.57 Diagonal retracts . . . 2058
4.9.58 Exercise 8.20 — self-embeddings of a domain . . . 2059
4.9.59 A-sharp on lists . . . 2060
4.9.60 A-sharp (more) . . . 2071
4.9.61 Exercise 8.21 — lists of a projection . . . 2076
4.9.62 Example C below B . . . 2076
4.9.63 Exercise 8.22 — comparing B and C . . . 2088
4.9.64 Fix operator . . . 2089
4.9.65 Exercise 8.23 — initial algebra inside U . . . 2094
4.9.66 Coupled fixed points . . . 2095
4.9.67 Exercise 8.24 — coupled domain equations . . . 2104
4.9.68 Reflexive domain . . . 2105
4.9.69 Exercise 8.25 — reflexive function space . . . 2113
4.9.70 U apply and U lam . . . 2114
4.9.71 Exercise 8.26 — untyped calculus in U . . . 2116
4.9.72 Polymorphic type . . . 2116
4.9.73 Infinite product on D . . . 2126
4.9.74 Sub on U . . . 2127

4.9.75 Infinite product on U . . . 2130
4.9.76 Exercise 8.27 — infinite cartesian products . . . 2133

5 Information Systems (1982) ✓ 2134
5.1 Introduction . . . 2135
5.2 Information systems . . . 2137
5.2.1 Introduction . . . 2137
5.2.2 Definition 2.1 . . . 2138
5.2.3 Lower-bound entailment . . . 2140
5.2.4 A first example . . . 2140
5.2.5 Interval tokens . . . 2141
5.2.6 Satisfaction . . . 2142
5.2.7 A second example . . . 2144
5.2.8 Partial-function tokens . . . 2144
5.2.9 Partial-function system . . . 2145
5.2.10 A third example . . . 2147
5.2.11 Definition 2.2 . . . 2148
5.2.12 Finite union . . . 2150
5.2.13 Proposition 2.3 . . . 2155
5.3 The elements of a system . . . 2156
5.3.1 Introduction . . . 2157
5.3.2 Definition 3.1 . . . 2158
5.3.3 Closure . . . 2160
5.3.4 Total elements . . . 2161
5.3.5 Top element . . . 2161
5.3.6 Remarks . . . 2163
5.4 Domains as lattices and as topological spaces . . . 2164
5.4.1 Introduction . . . 2165
5.4.2 Binary meet . . . 2166
5.4.3 Factoid 4.1: lattice / binary meets . . . 2168
5.4.4 Family infima . . . 2169
5.4.5 Factoid 4.2: family infs . . . 2171
5.4.6 Finite consistency . . . 2171
5.4.7 Deductive closure . . . 2173
5.4.8 Family union carrier . . . 2174
5.4.9 Family suprema . . . 2175
5.4.10 Join . . . 2176
5.4.11 Factoid 4.3: joins / conditional sups . . . 2177
5.4.12 Chains . . . 2178
5.4.13 Directed families . . . 2179
5.4.14 Directed suprema . . . 2180
5.4.15 Chain suprema . . . 2182
5.4.16 Factoid 4.4: chains & directed sups . . . 2182
5.4.17 Bottom as empty closure . . . 2183
5.4.18 Finite approximants . . . 2184
5.4.19 Factoid 4.5: finite approximants . . . 2186

5.4.20 Scott continuous maps . . . 2186
5.4.21 The basic Scott-opens . . . 2188
5.4.22 Approximable maps as Scott continuous . . . 2189
5.4.23 Factoid 4.6: topology / Scott continuity . . . 2192
5.5 Approximable mappings between domains . . . 2194
5.5.1 Introduction . . . 2195
5.5.2 Definition 5.1: approximable mappings . . . 2196
5.5.3 Element map . . . 2198
5.5.4 Definition 5.2: image / function value . . . 2201
5.5.5 Proposition 5.3: element maps / pointwise comparison . . . 2202
5.5.6 Identity map . . . 2203
5.5.7 Proposition 5.4: identity mapping . . . 2204
5.5.8 Composition . . . 2205
5.5.9 Proposition 5.5: composition . . . 2206
5.5.10 Constant map . . . 2207
5.5.11 Proposition 5.6: constant maps . . . 2209
5.6 Products of domains . . . 2210
5.6.1 Introduction . . . 2211
5.6.2 Product token predicate . . . 2212
5.6.3 Decidability of product tokens . . . 2212
5.6.4 Product tokens . . . 2213
5.6.5 Equality on product tokens . . . 2214
5.6.6 Product bottom . . . 2214
5.6.7 First-component insert commutes . . . 2215
5.6.8 Second-component insert commutes . . . 2216
5.6.9 Fold membership for first components . . . 2216
5.6.10 Fold membership for second components . . . 2217
5.6.11 First projection of product sets . . . 2218
5.6.12 Second projection of product sets . . . 2221
5.6.13 Product entailment . . . 2224
5.6.14 Definition 6.1: product system . . . 2225
5.6.15 Product library . . . 2231
5.6.16 Left injection . . . 2232
5.6.17 Right injection . . . 2233
5.6.18 Left lift . . . 2234
5.6.19 Right lift . . . 2236
5.6.20 Pairing map . . . 2238
5.6.21 Proposition 6.2: projections and pairing . . . 2240
5.7 Sums of domains . . . 2242
5.7.1 Sum tokens . . . 2243
5.7.2 Equality on sum tokens . . . 2244
5.7.3 Sum bottom . . . 2245
5.7.4 Left-component insert . . . 2245
5.7.5 Right-component insert . . . 2246
5.7.6 Left insert commutes . . . 2247

5.7.7 Right insert commutes . . . 2247
5.7.8 Fold membership for left components . . . 2248
5.7.9 Fold membership for right components . . . 2250
5.7.10 Left projection of sum sets . . . 2251
5.7.11 Right projection of sum sets . . . 2254
5.7.12 Sum consistency . . . 2258
5.7.13 Sum entailment . . . 2259
5.7.14 Definition 6.3: separated sum . . . 2260
5.7.15 Empty sum consistency . . . 2263
5.7.16 Sum library . . . 2264
5.7.17 Left sum lift . . . 2265

1 Introduction

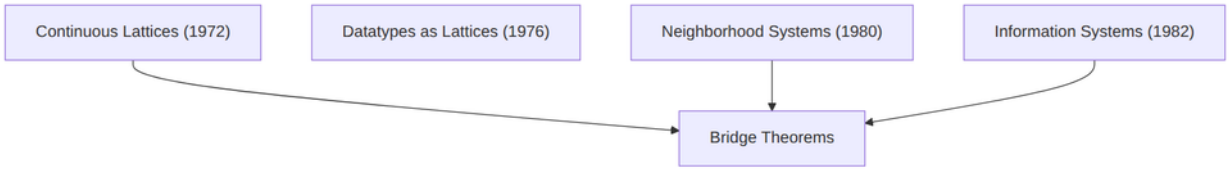

Figure 1: Introduction.

This combined library is registered with Palomar as **PALOMAR-2026-11-12-000010**, version 1 [1].

DomainTheory is a single Lean 4 / Mathlib library (v4.36.0-rc2, `lake build` green, no `sorry`) assembled from five prior Palomar-registered formalizations, each with a public GitHub home under `catskillsresearch`, and vendored in the DomainTheory GitHub repository [2] under `vendor/` for provenance:

- *Continuous Lattices* (1972) — Palomar [3], GitHub [4], and arXiv preprint [5];
- *Data Types as Lattices* (1976) — Palomar [6] and GitHub [7];
- neighbourhood systems / PRG-19 (1980) — Palomar [8] and GitHub [9];
- information systems (1982) — Palomar [10] and GitHub [11];
- cross-presentation bridges (`scott_models`) — Palomar [12] and GitHub [13].

The working Lean is the golfed `DomainTheory/` tree: `ContinuousLattice` ← 1972, `DataTypesAsLattices` ← 1976, `NeighbourhoodSystems` ← 1980, `InformationSystems` ← 1982, `BridgeTheorems` ← `scott_models`. Comparator (`Challenge.lean` / `Solution.lean` / `comparator.json`) validates (i) the cross-presentation bridges of [12] (1972 continuous-lattice / 1980 neighbourhood / 1982 information-system isomorphisms, including $D \simeq_o$ RoundFilter $\simeq_o$ RoundInfoSysElement and the S-expression equation $|T| \simeq_o |A + (T \times T)|$), and (ii) the selected *Data Types as Lattices* (1976) declarations of [6]. That 1976 selection is not only the retract and algebraic-lattice development on $\mathbf{P}\omega$: it also covers Scott's computability apparatus for the universal domain (the language LAMBDA, enumeration and recursion, definability, and enumeration degrees as combinatory subalgebras) and the descriptive-set style classification of subsets of $\mathbf{P}\omega$ (open, closed, $\mathfrak{G}_\delta$, Boolean, and related classes characterized as fibres of continuous maps). The golfed library preserves those validated results under Mathlib-style names. The Lean sources and frozen vendor trees live in [2]; this document is the accompanying CMU-CS technical report.

Author contributions. Lars Warren Ericson — primary formalization engineer (all Lean 4, AI-assisted proof architecture, repository assembly); Dana S. Scott — author of the original source mathematics (1972–1982), project sponsorship, historical context, and high-level advisory oversight of formalization scope; Vijay D'Silva and Brian Milnes — project initiation, pre-submission review, and advisory feedback on repository formatting and technical report generation. Source-paper authorship is distinct from combined-library co-authorship; Scott, D'Silva, and Milnes did not write the Lean.

2 Continuous Lattices (1972) ✓

Starting from the topological point of view a certain wide class of T_0-spaces is introduced having a very strong extension property for continuous functions with values in these spaces. It is then shown that all such spaces are complete lattices whose lattice structure determines the topology - these are the *continuous lattices* - and every such lattice has the extension property. With this foundation the lattices are studied in detail with respect to projections, subspaces, embeddings, and constructions such as products, sums, function spaces, and inverse limits. The main result of the paper is a proof that every topological space can be embedded in a continuous lattice which is homeomorphic (and isomorphic) to its own function space. The function algebra of such spaces provides mathematical models for the Church-Curry λ-calculus.

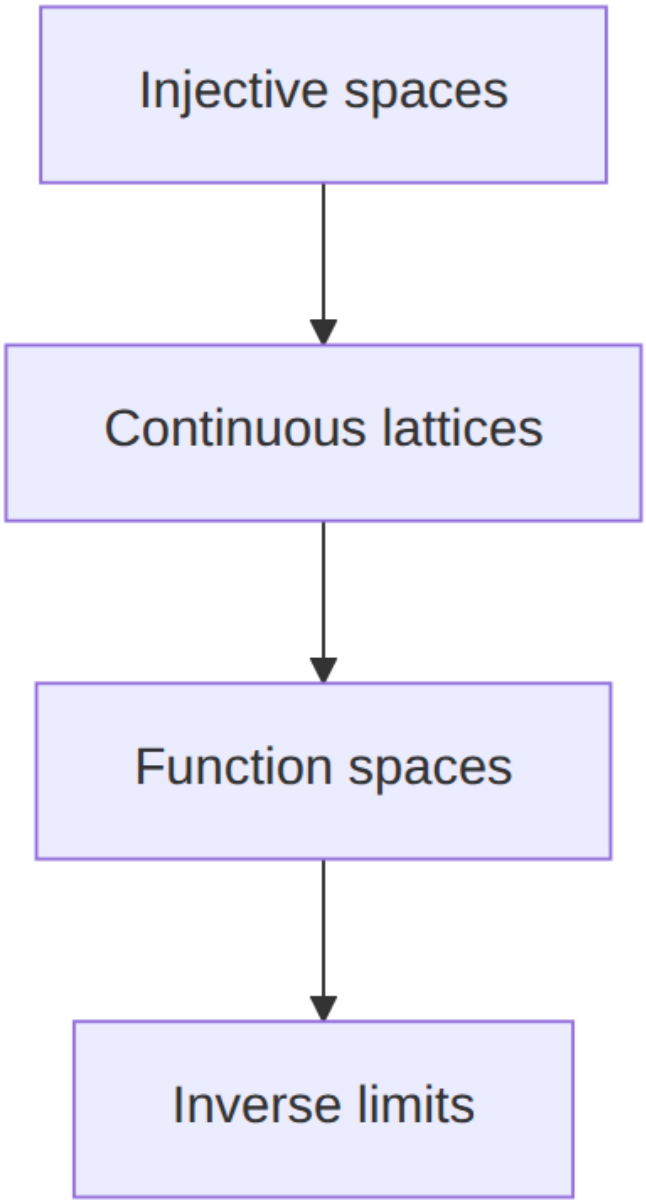

Figure 2: Continuous Lattices (1972) ✓.

2.1 Introduction ✓

Through a roundabout chain of mathematical events I have become interested in T_0-spaces, those topological spaces satisfying the weakest separation axiom to the effect that two distinct points cannot share the same system of open neighborhoods. These spaces seem to have been originally suggested by Kolmogoroff and were introduced first in [14]. Subsequent topology textbooks have dutifully recorded the definition but without much enthusiasm: mainly the idea is introduced to provide exercises. In the book [15] for example,

T_0-spaces are called *feebly semi-separated spaces*, which surely is a term expressing mild contempt. Some interest has been shown in finite T_0-spaces (finite T_1-spaces are necessarily discrete), but generally topology seems to go better under at least the Hausdorff separation axiom. The reason for this is no doubt the strong motivation we get from geometry, where points *are* points and where distinct points *can* be separated.

What I hope to show in this paper is that from a less geometric point of view T_0-spaces can be not only interesting but also natural. The interest for me lies in the construction of *function spaces*, and the main result is the production of a large number of T_0-spaces D such that D and $[D \to D]$ are *homeomorphic*. Here $[D \to D]$ is the space of all continuous functions from D into D with the topology of pointwise convergence (the product topology). It will be shown that every space can be embedded in such a space D, and that D can be chosen to have quite strong extension properties for D-valued continuous functions. These properties make D most convenient for applications to logic and recursive function theory, which was the author's original motivation. Some of the facts about these spaces seem to be most easily proved with the aid of some lattice theory, a circumstance that throws new light on the connections between topology and lattices. In fact, the required spaces are at the same time complete lattices whose topology is determined by the lattice structure in a special way, whence my title.

2.2 Injective spaces ✓

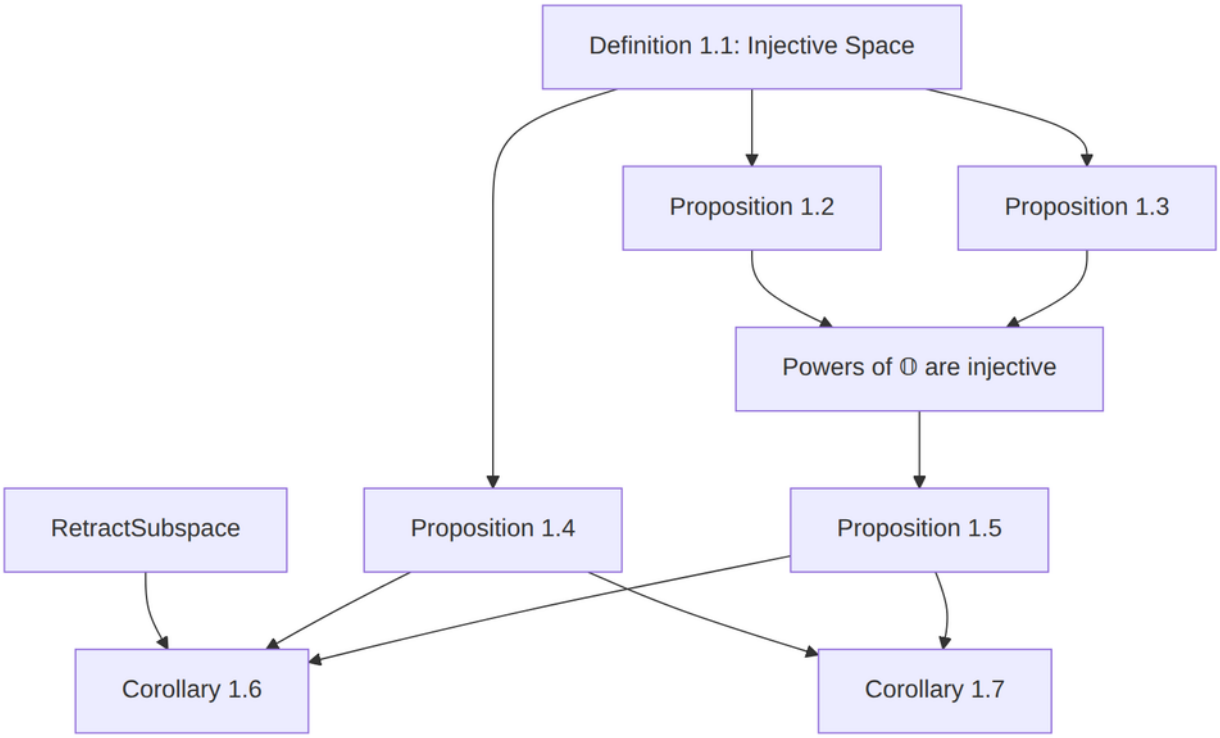

Figure 3: Injective spaces ✓.

All spaces are T_0-spaces, and we begin by defining a class of spaces to be called *injective*.

2.2.1 Definition 1.1: Injective Space ✓

1.1 Definition. A T_0-space D is *injective* iff for arbitrary spaces X and Y if $X \subseteq Y$ as a subspace, then every continuous function $f : X \to D$ can be extended to a continuous function $\bar{f} : Y \to D$. As a diagram we have:

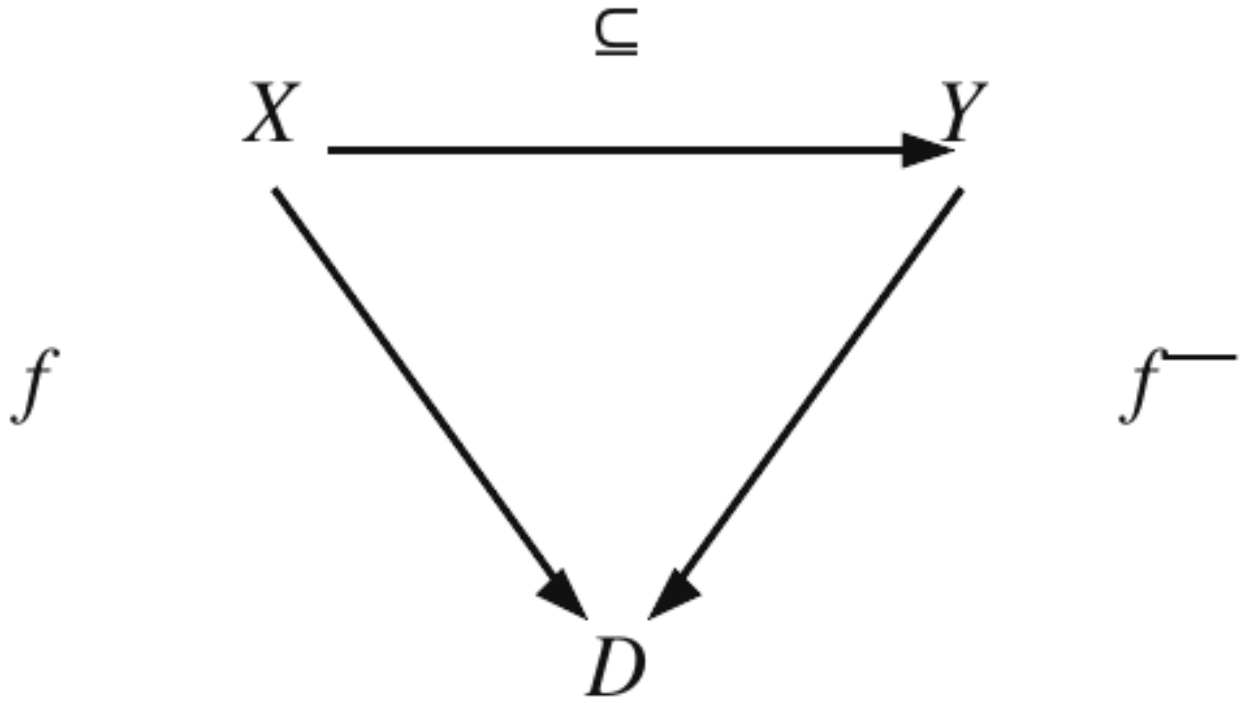

Figure 4: Injective extension: X subspace of Y, continuous maps f from X to D and f bar from Y to D.

Some people will object to this terminology because I use the subspace relationship rather than a monomorphism in the category of T_0-spaces and continuous maps. However, only the trivial 1-point space is injective in the sense of monomorphisms in that category, and so the notion is uninteresting. If the reader prefers another terminology, I do not mind. As we shall see these spaces have very strong retraction properties.

      IsEmbedding e → ∀ f : C(X, D), ∃ g : C(Y, D), ∀ x, g (e x) = f x
```

2.2.2 Proposition 1.2 ✓

A slightly less trivial example of an injective space is the 2-point space $\mathbb{O}$ with "points" $\bot$ and $\top$ where $\top$ is open but $\bot$ is not. (This space is sometimes called the *Sierpinski Space*.)

1.2 Proposition. The space $\mathbb{O}$ is injective.

Proof: As is obvious, the continuous maps $f : X \to \mathbb{O}$ are in a one-one correspondence with the open subsets of X (consider $f^{-1}(\top)$). If $X \subseteq Y$ as a subspace, then an open subset of X is the restriction of some open subset of Y. Thus any $f : X \to \mathbb{O}$ can be extended to $\bar{f} : Y \to \mathbb{O}$. □

2.2.3 Proposition 1.3 ✓

1.3 Proposition. The Cartesian product of any number of injective spaces is injective under the product topology.

Proof: The argument is standard. A map into the product can be projected onto each of the factors. Each of these projections can be extended. Then the separate maps can be put together again to make the required extended map into the product. □

We now have a large number of injective spaces, and further examples could be found using the next fact.

2.2.4 Powers of $\mathbb{O}$ are injective ✓

Lemma. Powers of $\mathbb{O}$ are injective.

Proof. Let I be any index set and let

$$D = \mathbb{O}^I$$

be the Cartesian power of the two-point space $\mathbb{O}$ with the product topology. Each factor $\mathbb{O}$ is injective by **1.2**. By **1.3**, the product of injective spaces is injective under the product topology, so D is injective. □

Proposition 1.5 applies this lemma with $I = \mathfrak{O}$, the open subsets of the given T_0-space.

2.2.5 Proposition 1.4 ✓

1.4 Proposition. A retract of an injective space is injective.

Proof: Let D be injective. By a retract of D we understand a subspace $D' \subseteq D$ for which there exists a retraction map $j : D \to D'$ such that

$$D' = \{x \in D : j(x) = x\}.$$

Then if $f : X \to D'$ and $X \subseteq Y$, we have $f : X \to D$ as a continuous map also. Taking $\bar{f} : Y \to D$, we have only to form

$$j \circ \bar{f} : Y \to D'$$

to show that D' is injective. □

The relationship between arbitrary T_0-spaces and the injective spaces is given by the embedding theorem.

2.2.6 Proposition 1.5 ✓

1.5 Proposition. Every T_0-space can be embedded in an injective space; in fact, in a Cartesian power of the 2-element space $\mathbb{O}$.

Proof: The proof is well known (cf. [15], Theorem 26B.9, p. 484.) But we give the argument for completeness sake. Let X be the given space, and let $\mathfrak{O}$ be the class of open subsets of X. Let

$$D = \mathbb{O}^{\mathfrak{O}}$$

be the Cartesian power of $\mathbb{O}$. Then D is injective by 1.3. Define the map $e : X \to D$ by:

$$e(x)(U) = \begin{cases} \top & \text{if } x \in U, \\ \bot & \text{if } x \notin U, \end{cases}$$

for $x \in X$ and $U \in \mathfrak{O}$. This map e is continuous in view of the topology given to $\mathbb{O}$ and to D. The map e is one-one, because X is T_0. Finally, if $U \subseteq X$ is open, then

$$e(U) = e(x) : x \in U \quad = e(x) : e(x)(U) = \top = e(X) \cap t \in D : t(U) \in \top,$$

which shows that the image $e(U)$ is open in the subspace $e(X) \subseteq D$. Therefore $e : X \to D$ is an embedding of X as a subspace in D. □

2.2.7 RetractSubspace ✓

Corollary 1.6 characterizes injective spaces as retracts of powers of $\mathbb{O}$. The Lean development packages "`D` is a subspace of a larger space and the inclusion splits by a continuous retraction" as `RetractSubspace D' D`: a continuous section `D' → D` that is an embedding, together with a retraction `D → D'` fixing the subspace pointwise.

Corollary 1.6 then states that `D` is injective if and only if it is such a retract of some power `ι → Prop`.

```

2.2.8 Corollary 1.6 ✓

1.6 Corollary. The injective spaces are exactly the retracts of the Cartesian powers of $\mathbb{O}$.

Proof: Such a retract is injective by 1.4. If D is injective, then it is (homeomorphic to) a subspace of a power of $\mathbb{O}$. But since D is injective the identity function on the subspace to itself can be extended to the whole of the power of $\mathbb{O}$ providing the required retraction. □

2.2.10 Absolute retracts ✓

As a result of these very elementary considerations, the injective spaces could be called *absolute retracts*, if one remembers to modify the standard definitions by using *arbitrary* subspaces rather than just *closed* subspaces. Note too that it is easy to show that the only continuous maps $e : X \to Y$ for which the extension property

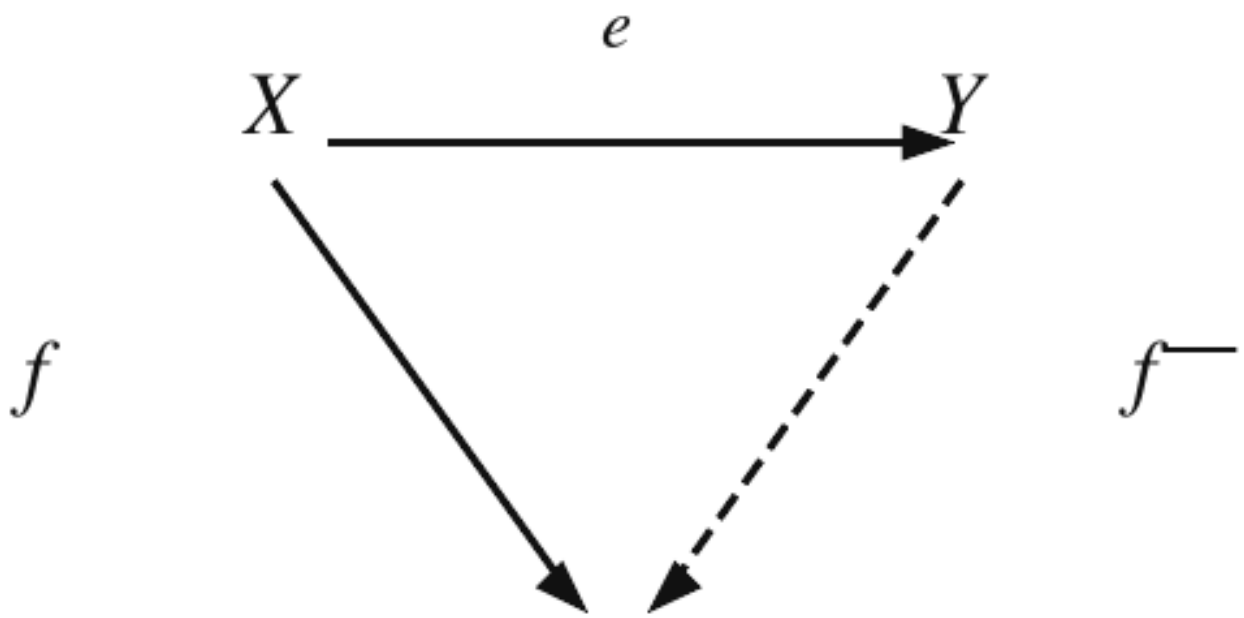

Figure 5: Extension triangle: X to Y by e, f from X to O, dashed f bar from Y to O.

could hold for *all* continuous $f : X \to \mathbb{O}$ are embeddings as subspaces.

Thus it would seem that we have a reasonably good initial grasp of the notion of injective spaces, but further constructions are considerably facilitated by the introduction of the lattice structure.

2.3 Continuous lattices ✓

Scott develops specialization, Scott-open sets, Scott topology, monotone nets, and Proposition 2.1 in Specialization order; the way-below relation, Proposition 2.2, and Definition 2.3 in Way-below relation. Proposition 2.4 through Theorem 2.12, idempotent fixed points, the order-iso and specialization lemmas used in inverse limits, and the post-theorem remarks are in Continuous lattice. Scott maps and Propositions 2.8–2.11, with their proof notes, treat Scott continuity, products, and retractions on continuous lattices on the way to Proposition 2.11 and Theorem 2.12.

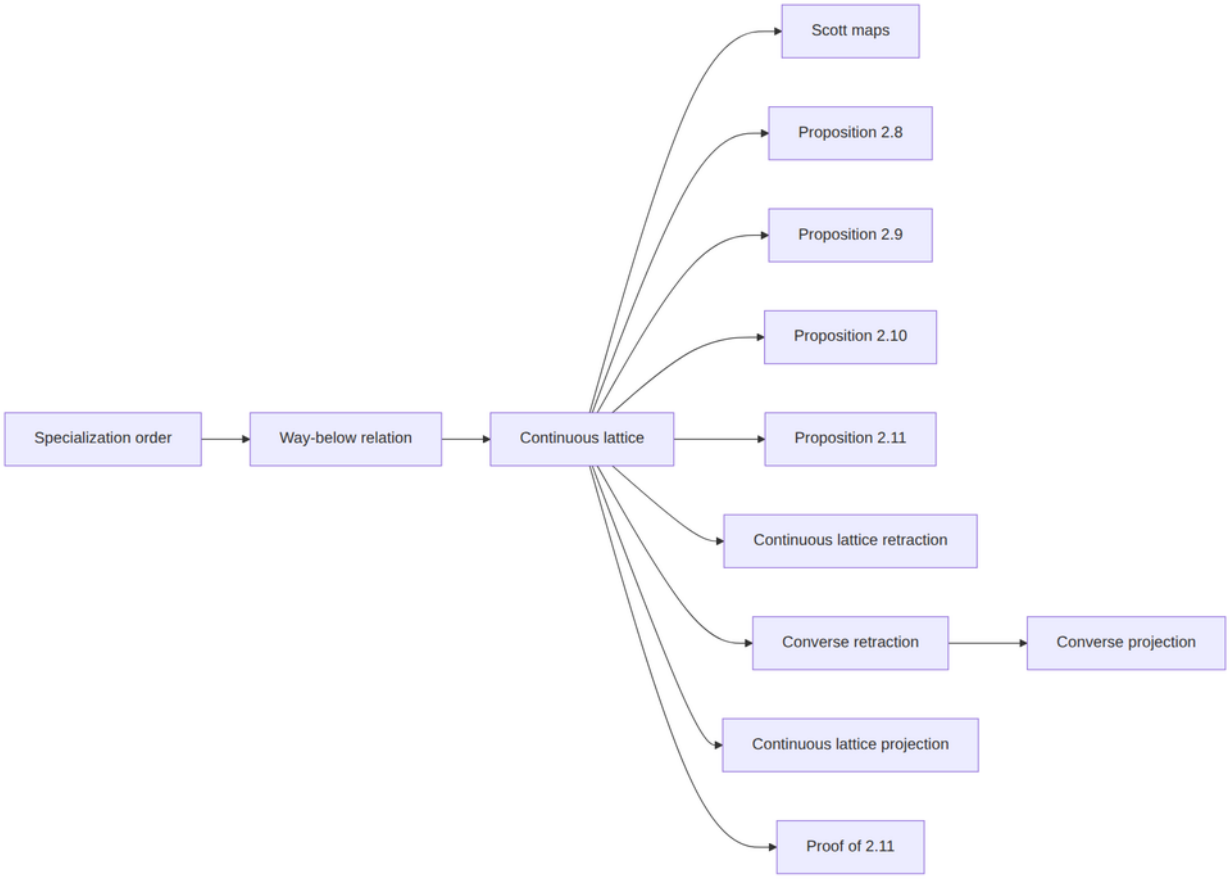

Figure 6: Continuous lattices ✓.

2.3.1 Specialization order ✓

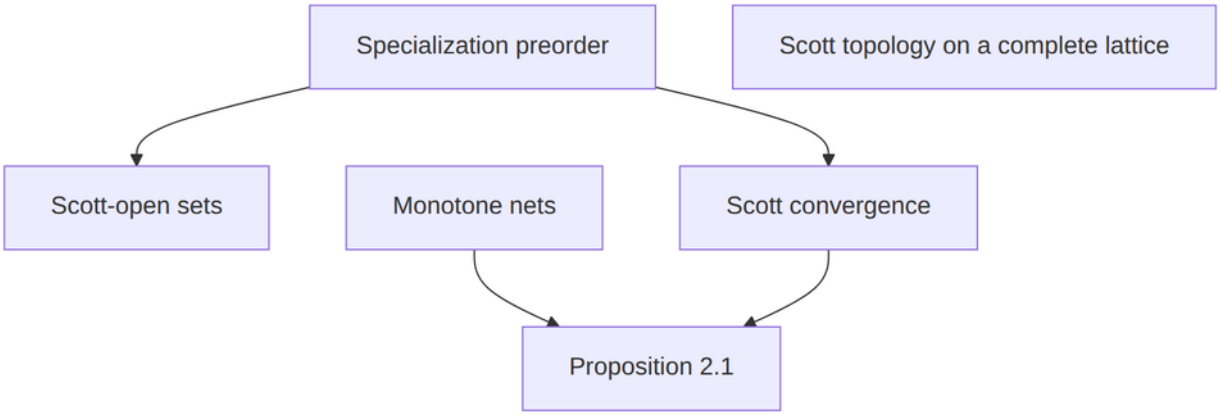

Figure 7: Specialization order ✓.

Specialization preorder Every T_0-space becomes a partially ordered set under the definition:

$$x \sqsubseteq y \text{ iff whenever } x \in U \text{ and } U \text{ is open, then } y \in U.$$

We call relation $\sqsubseteq$ **the specialization preorder** on X. It is reflexive and transitive on every topological space; on a T_0-space it is antisymmetric, and that antisymmetry is exactly the T_0-axiom.

In the converse direction, every partially ordered set $\langle X, \sqsubseteq \rangle$ can be so obtained, for we have only to define $U \subseteq X$ as being open if it satisfies the condition:

(i) whenever $x \in U$ and $x \sqsubseteq y$, then $y \in U$.

The axioms for partial order make X a T_0-space, because for any $y \in X$ the set

$$\{x \in X : x \not\sqsubseteq y\}$$

is open. This connection is not very interesting, however.

The formalization names the same predicate `SpecializationPreorder`. The lemmas below are the library tools used in the inverse-limit specialization characterization and in Theorem 2.12.

Notation. For the specialization preorder above, Mathlib also writes $y \rightsquigarrow x$ when y lies in every open neighborhood of x (the relation `Specializes`, read "y specializes x"). The arrow points from the larger point toward the smaller one; Scott's $x \sqsubseteq y$ is the same comparison with the opposite order of arguments.

Lemma (`SpecializationPreorder.iff_specializes`). For x, y in a topological space, $x \sqsubseteq y$ iff $y \rightsquigarrow x$.

Proof. Both sides mean: whenever U is open and $x \in U$, then $y \in U$. This is `specializes_iff_forall_open`. □

Lemma (`SpecializationPreorder.scott_iff`). On a complete lattice D with the Scott topology `scottTopologicalSpace`, for all $x, y \in D$,

$$x \sqsubseteq y \text{ (specialization preorder)} \iff x \le y \text{ (lattice order)}.$$

Proof. ($\Rightarrow$) Suppose $x \sqsubseteq y$ but $x \not\le y$. The set $U = \{z \in D : z \not\le y\}$ is Scott-open (`ScottOpen.not_le`). We have $x \in U$ since $x \not\le y$, so $y \in U$ by the specialization preorder; that is $y \not\le y$, a contradiction. Hence $x \le y$.

($\Leftarrow$) Suppose $x \le y$ and U is Scott-open with $x \in U$. Since U is an upset, $y \in U$. Thus $x \sqsubseteq y$. □

Lemma (`SpecializationPreorder.map`). If $x \sqsubseteq y$ in X and $f : X \to Y$ is continuous, then $f(x) \sqsubseteq f(y)$ in Y.

Proof. Let $V \subseteq Y$ be open with $f(x) \in V$. Then $x \in f^{-1}(V)$ and $f^{-1}(V)$ is open in X. From $x \sqsubseteq y$ we get $y \in f^{-1}(V)$, hence $f(y) \in V$. □

end SpecializationPreorder

end DomainTheory.ContinuousLattice
```

Scott-open sets We shall find that most of the facts about the topology of the spaces we are concerned with here can be expressed in terms of least upper bounds (lubs). It is not always the case, however, that lubs are limits. Thus, for a partially ordered set X, we impose a further restriction on its topology beyond condition (i) for saying when a subset U is open:

(ii) whenever $S \subseteq X$ is *directed*, $\bigsqcup S$ exists, and $\bigsqcup S \in U$, then $S \cap U \neq \emptyset$.

By a directed subset of X we of course mean that it is directed in the sense of the partial ordering $\sqsubseteq$. Note that in this paper directed sets are always *non-empty*.

Scott-open sets are exactly the open sets of `scottTopologicalSpace`.

On a complete lattice D we use the lattice order $\leq$ (for the specialization order on D with the Scott topology, this agrees with $\sqsubseteq$; see `SpecializationPreorder.scott_iff`). Condition (i) is that U

be an *upper set* (an upset): if $a \in U$ and $a \le b$, then $b \in U$. The formalization packages (i) and (ii) for subsets of D as `ScottOpen`. The lemmas below are the library tools that justify that equivalence.

Definition (`ScottOpen`). A subset $U \subseteq D$ is **Scott-open** when U is an upper set and, for every nonempty directed $S \subseteq D$, if $\sup S \in U$ then $S \cap U \neq \emptyset$.

Lemma (`ScottOpen.isUpperSet`). If U is Scott-open, then U is an upper set.

Proof. This is the first component of the definition. □

Lemma (`ScottOpen.inter`). If U and V are Scott-open, then $U \cap V$ is Scott-open.

Proof. $U \cap V$ is an upper set. If $\sup S \in U \cap V$ for directed nonempty S, then $\sup S \in U$ and $\sup S \in V$. By Scott-openness of U and V there are $s_1, s_2 \in S$ with $s_1 \in U$ and $s_2 \in V$. Directedness gives $s_3 \in S$ with $s_3 \ge s_1, s_2$, hence $s_3 \in U \cap V$. □

Lemma (`ScottOpen.univ`). The whole lattice D is Scott-open.

Proof. D is an upper set. If $\sup S \in D$ for nonempty S, any $s \in S$ lies in D. □

Lemma (`ScottOpen.sUnion`). If every member of a family $\mathcal{C}$ of subsets of D is Scott-open, then $\bigcup \mathcal{C}$ is Scott-open.

Proof. A union of upper sets is an upper set. If $\sup S$ lies in some $U \in \mathcal{C}$ with U Scott-open, pick $s \in S \cap U$; then $s \in \bigcup \mathcal{C}$. □

Lemma (`ScottOpen.iff_dirSupInacc`). For $U \subseteq D$,

$$U \text{ is Scott-open} \iff U \text{ is an upper set and } U \text{ is inaccessible under directed sups}$$

(in Mathlib: `IsUpperSet U ∧ DirSupInacc U`).

Proof. Both sides unfold to the same upset condition and the same "if $\sup S \in U$ for directed nonempty S, then $S \cap U \neq \emptyset$" clause, phrased either with `sSup` or with `IsLUB`. □

Lemma (`ScottOpen.preimage_orderIso`). If $e : A \to B$ is an order isomorphism and $U \subseteq B$ is Scott-open, then $e^{-1}(U) \subseteq A$ is Scott-open.

Proof. Upper-set condition pulls back along monotone e. If $\sup S \in e^{-1}(U)$ for directed nonempty $S \subseteq A$, then $\sup(e'' S) = e(\sup S) \in U$; Scott-openness of U gives $s \in S$ with $e(s) \in U$, i.e. $s \in e^{-1}(U)$. □

Lemma (`ScottOpen.isOpen_iff`). With the Scott topology `scottTopologicalSpace` on D, a set $U \subseteq D$ is topologically open iff U is Scott-open.

Proof. Rewrite via `ScottOpen.iff_dirSupInacc` and the definition of `scottTopologicalSpace` as `Topology.scott D Set.univ`; conclude with Mathlib's `IsScott.isOpen_iff_isUpperSet_and_dirSupInaccOn`. □

Lemma (`ScottOpen.not_le`). For any $L \in D$, the set $U = \{z \in D : z \not\le L\}$ is Scott-open.

Proof. If $a \in U$ and $a \le b$, then $b \not\le L$ (otherwise $a \le b \le L$). If $\sup S \in U$ for directed nonempty S but $S \cap U = \emptyset$, then every $s \in S$ satisfies $s \le L$, so $\sup S \le L$, contradicting $\sup S \in U$. □

Lemma (`ScottOpen.wayBelow`). For $x \in D$, the set

$$\{z \in D : \exists U \subseteq D,\ U \text{ Scott-open} \wedge z \in U \wedge U \subseteq \{w : x \le w\}\}$$

is Scott-open. Once the way-below relation $x \ll y$ is defined (`WayBelow`), this set is $\{z : x \ll z\}$; see `WayBelow.lean`.

Proof. If a belongs to a Scott-open U with $U \subseteq \{w : x \le w\}$ and $a \le b$, then $b \in U$ by the upset property, so b is in the same set. If $\sup S$ belongs to the set, pick a witness Scott-open U with $\sup S \in U \subseteq \{w : x \le w\}$. By Scott-openness of U, some $s \in S$ lies in U, and the same U witnesses s in $\{z : x \ll z\}$ in the existential form. □

Scott topology on a complete lattice The sets satisfying (i) and (ii) form the *induced topology* on a partially ordered set X, which is still a T_0-space because the sets $\{x \in X : x \not\sqsubseteq y\}$ remain open even in the

sense of (ii). Obviously a directed set $S \subseteq X$ can be regarded as a net, and now in view of (ii) it follows that S converges to $\bigsqcup S$ — if this lub exists.

On a complete lattice D, the formalization names this induced topology **`scottTopologicalSpace`**: a concrete `TopologicalSpace D` built from Mathlib's Scott construction, **not** a global typeclass default (so we can still name Scott explicitly in later theorems and compare other topologies on the same D).

Lemma (`scottTopologicalSpace.t0Space`). D is a T_0-space for the topology `scottTopologicalSpace`.

Proof. After `let : TopologicalSpace D := scottTopologicalSpace`, implicit `[TopologicalSpace D]` in the Scott library matches the topology in the goal `@T0Space D scottTopologicalSpace`; then `IsScott` holds by definition and Mathlib supplies `T0Space`. (That `let` line does not pass arguments into the def—it registers the def as the local topology instance for the proof block.) □

Monotone nets What *is* interesting in topological spaces is *convergence* and the properties of *limit points*. We shall discuss limits in terms of *nets*, in particular in terms of *monotone nets*. A monotone net in a T_0-space X is a function

$$x : I \to X$$

where $\langle I, \leq \rangle$ is a directed set and where $i \leq j$ implies $x_i \sqsubseteq x_j$ for all $i, j \in I$. In a T_1-space a monotone net is constant (hence, uninteresting) because the $\sqsubseteq$-relation is the identity.

On a complete lattice D, the library records the same idea as **`MonotoneNet`**: for a directed index type ι and a net $x : \iota \to D$, require **`Monotone x`** (i.e. $i \le j \Rightarrow x_i \le x_j$ in the lattice order). With the Scott topology, $\sqsubseteq$ agrees with $\le$ (`SpecializationPreorder.scott_iff`); **Proposition 2.1** is stated using `MonotoneNet` and `ScottConvergesTo`.

`MonotoneNet.lean`

```
module

variable {ι : Type u} [Preorder ι] [IsDirected ι (· ≤ ·)]

class MonotoneNet (x : ι → D) : Prop where
  out : Monotone x

end DomainTheory.ContinuousLattice
```

Scott convergence As usual (cf. [16, p. 66]) we say that a net x *converges* to an element y iff whenever U is open and $y \in U$, then for some $i \in I$ we have $x_j \in U$ for all $j \ge i$. Note that a monotone net x converges to each of its terms x_i. Suppose that a monotone net x converges to an element y which is an upper bound to all the terms of x. Then y must be the *least upper bound*, which we write as:

$$y = \bigsqcup \{x_i : i \in I\}.$$

To see this, assume that z is any other upper bound with $x_i \sqsubseteq z$ for all $i \in I$. If U is open and $y \in U$, then $x_i \in U$ for some $i \in I$. But then $z \in U$, and so $y \sqsubseteq z$ follows.

On a complete lattice D with directed index type ι, the library names Scott's convergence condition **`ScottConvergesTo`**: for a net $x : \iota \to D$ and a point $y \in D$,

$$\text{`ScottConvergesTo x y`} \iff \forall U,\ U \text{ Scott-open} \wedge y \in U \Rightarrow \text{eventually } x_j \in U.$$

"Open" in the induced Scott sense is **`ScottOpen U`**; the same sets are open for the topology **`scottTopologicalSpace`** (`ScottOpen.isOpen_iff`). The specialization preorder in that topology agrees with lattice $\le$ (`SpecializationPreorder.scott_iff`). Scott's paragraph above is the motivation for the biconditional in **Proposition 2.1**, which is proved in `proposition_2_1.lean` and stated on the separate Proposition 2.1 note (together with **`MonotoneNet`**).

`ScottConvergesTo.lean`

```
module

public import DomainTheory.ContinuousLattice.WayBelow.ScottOpen

@[expose] public section

namespace DomainTheory.ContinuousLattice

universe u

variable {D : Type u} [CompleteLattice D]

variable {ι : Type u} [Preorder ι] [IsDirected ι (· ≤ ·)]

def ScottConvergesTo (x : ι → D) (y : D) : Prop :=
  ∀ U, ScottOpen U → y ∈ U → ∃ i, ∀ j ≥ i, x j ∈ U

end DomainTheory.ContinuousLattice
```

Proposition 2.1 We can summarize this discussion as follows.

2.1 Proposition. *In a partially ordered set X with the induced topology, a monotone net $x : I \to X$ with a least upper bound converges to an element $y \in X$ iff*

$$y \sqsubseteq \bigsqcup \{x_i : i \in I\}.$$

□

On a complete lattice D with directed index type ι, Scott's "induced topology" is the Scott topology **`scottTopologicalSpace`**: convergence is **`ScottConvergesTo`**, monotonicity is **`MonotoneNet x`**, and a least upper bound L of the net is **`IsLUB (range x) L`**. Under that topology, $\sqsubseteq$ is lattice $\leq$ (`SpecializationPreorder.scott_iff`), so Scott's condition is formalized as `ScottConvergesTo x y ↔ y ≤ L`. The module **`proposition_2_1`** is Scott's biconditional; the nested lemmas in namespace **`proposition_2_1`** are the two directions.

Lemma (`proposition_2_1.le_of_converges`). If `IsLUB (range x) L` and `ScottConvergesTo x y`, then $y \leq L$.

Proof. If $y \not\leq L$, then $y \in \{z : z \not\leq L\}$, which is Scott-open (`ScottOpen.not_le L`). Convergence gives a tail of the net in that set, contradicting that L bounds every term. □

Lemma (`proposition_2_1.of_le`). If ι is nonempty, `MonotoneNet x`, `IsLUB (range x) L`, and $y \leq L$, then `ScottConvergesTo x y`.

Proof. For Scott-open U with $y \in U$, the values $\{x_i\}$ form a directed set in the lattice order; $L = \bigsqcup x_i \in U$ since U is an upset, so Scott-openness yields some term in U, and monotonicity keeps all later terms in U. □

Theorem (`proposition_2_1`). If ι is nonempty, `MonotoneNet x`, and `IsLUB (range x) L`, then `ScottConvergesTo x y ↔ y ≤ L`.

Proof. `proposition_2_1.le_of_converges` and `proposition_2_1.of_le`. □

2.3.2 Way-below relation ✓

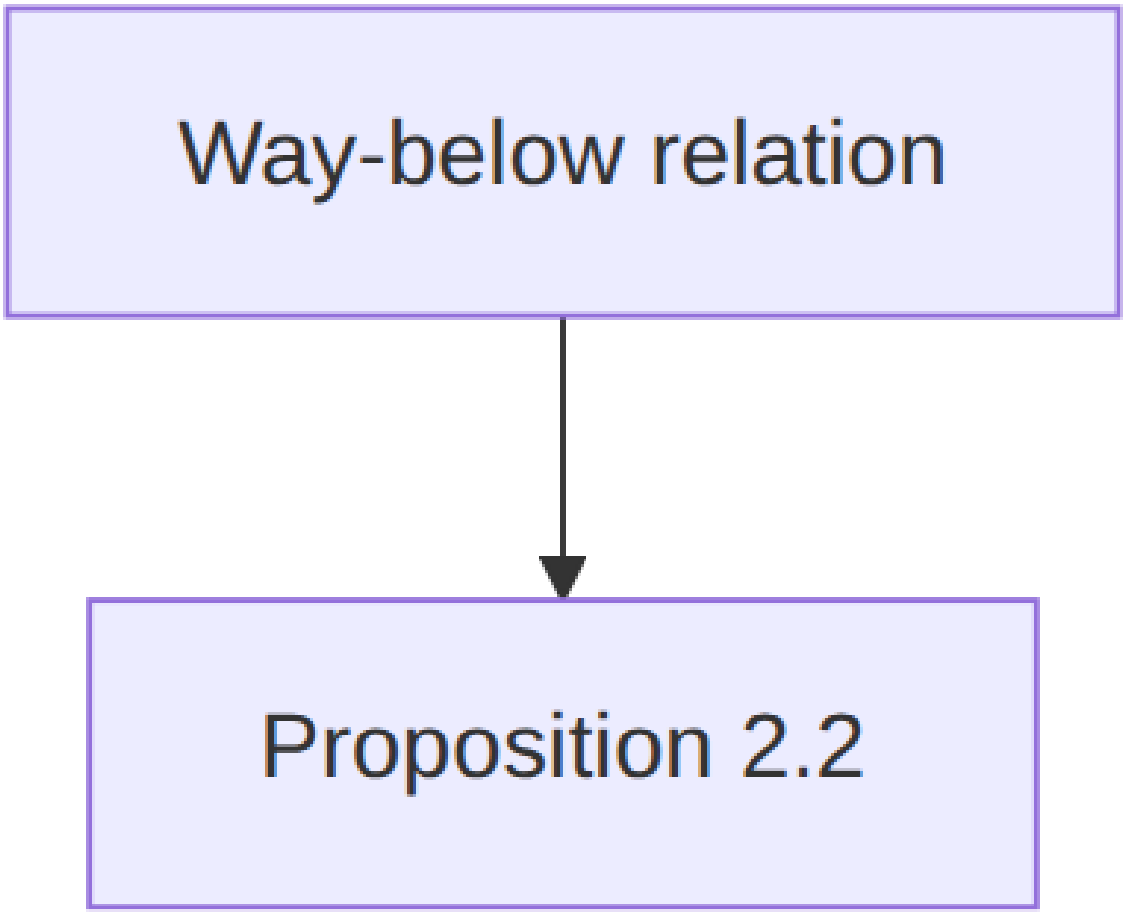

Figure 8: Way-below relation ✓.

Way-below relation Our main interest will lie with those partially ordered sets in which every subset has a lub: namely, *complete lattices*. If D is such a space we write $\bot = \bigsqcup \emptyset$ and $\top = \bigsqcup D$ for the smallest and largest elements (read: bottom and top). As is well known, greatest lower bounds must exist, for:

$$\sqcap S = \bigsqcup \{x \in D : x \sqsubseteq y\} \text{ for all } y \in S$$

gives the definition.

Given a complete lattice D we define

$$x \ll y \text{ iff } y \in \text{Int}\{z \in D : x \sqsubseteq z\},$$

where the interior is taken in the sense of the induced topology. The relation $x \ll y$ behaves somewhat like a strict ordering relation; at least its meaning is clearly that y should be definitely larger than x in the

partial ordering. Such a relation has many pleasant properties.

On a complete lattice D, the induced topology is the Scott topology **`scottTopologicalSpace`**; $\sqsubseteq$ is lattice $\leq$ (`SpecializationPreorder.scott_iff`). Scott's interior condition is equivalent to: there is a Scott-open set U with $y \in U$ and $U \subseteq \{z : x \leq z\}$ (i.e. $U \subseteq\!\uparrow x$). The library names that relation **`WayBelow`**; we write **`x`** $\ll$ **`y`** for `WayBelow x y`. The set $\{z : x \ll z\}$ is Scott-open (`ScottOpen.wayBelow`).

The elementary lemmas live in namespace **`WayBelow`** (same pattern as **`ScottOpen`**). **Proposition 2.2** is Scott's list (i)–(vii), proved in `proposition_2_2.lean` by calling these tools; see the Proposition 2.2 note.

Definition (`WayBelow`). $x \ll y$ iff $\exists U$, U Scott-open $\wedge y \in U \wedge U \subseteq \{z : x \leq z\}$.

Lemma (`WayBelow.bot`). $\bot \ll x$ for all $x \in D$.

Proof. Take $U = D$ (`ScottOpen.univ`). □

Lemma (`WayBelow.sup`). If $x \ll z$ and $y \ll z$, then $x \sqcup y \ll z$.

Proof. Intersect the two witnessing Scott-open sets (`ScottOpen.inter`). □

Lemma (`WayBelow.trans_le`). If $x \ll y$ and $y \leq z$, then $x \ll z$.

Proof. The same Scott-open witness works; $z \in U$ because U is an upset. □

Lemma (`WayBelow.le_trans`). If $x \leq y$ and $y \ll z$, then $x \ll z$.

Proof. Every $w \in U$ with $y \ll z$ satisfies $x \leq w$. □

Lemma (`WayBelow.le`). If $x \ll y$, then $x \leq y$.

Proof. $y \in U \subseteq\!\uparrow x$. □

Lemma (`WayBelow.self_iff_scottOpen_Ici`). $x \ll x$ iff $\uparrow x = \{z : x \leq z\}$ is Scott-open.

Proof. ($\Rightarrow$) A witness U for $x \ll x$ must equal $\uparrow x$. ($\Leftarrow$) Take $U = \uparrow x$. □

Lemma (`WayBelow.sSup_iff`). For nonempty directed $S \subseteq D$,

$$x \ll \sup S \iff \exists y \in S,\ x \ll y.$$

Proof. ($\Rightarrow$) Use the Scott-open witness and directed-sup accessibility in the definition of Scott-open. ($\Leftarrow$) If $x \ll y$ with $y \in S$, the witness for $x \ll y$ also works for $x \ll \sup S$. □

Lemma (`WayBelow.directedOn`). For each $y \in D$, the set $\{x : x \ll y\}$ is directed in the lattice order.

Proof. If $a, b \ll y$, then $a \sqcup b \ll y$ by `WayBelow.sup`. □

Lemma (`WayBelow.sInf`). If U is Scott-open and $y \in U$, then $\inf U \ll y$.

Proof. U itself witnesses $\inf U \ll y$: every $w \in U$ satisfies $\inf U \leq w$. □

Lemma (`WayBelow.map_orderIso`). If $e : A \to B$ is an order isomorphism and $x \ll y$ in A, then $e(x) \ll e(y)$ in B.

Proof. Pull back the Scott-open witness for $x \ll y$ along e^{-1} (`ScottOpen.preimage_orderIso`); membership and the $\uparrow$-subgraph condition follow from e and e^{-1} being order isomorphisms. □

2.3.3 Continuous lattice ✓

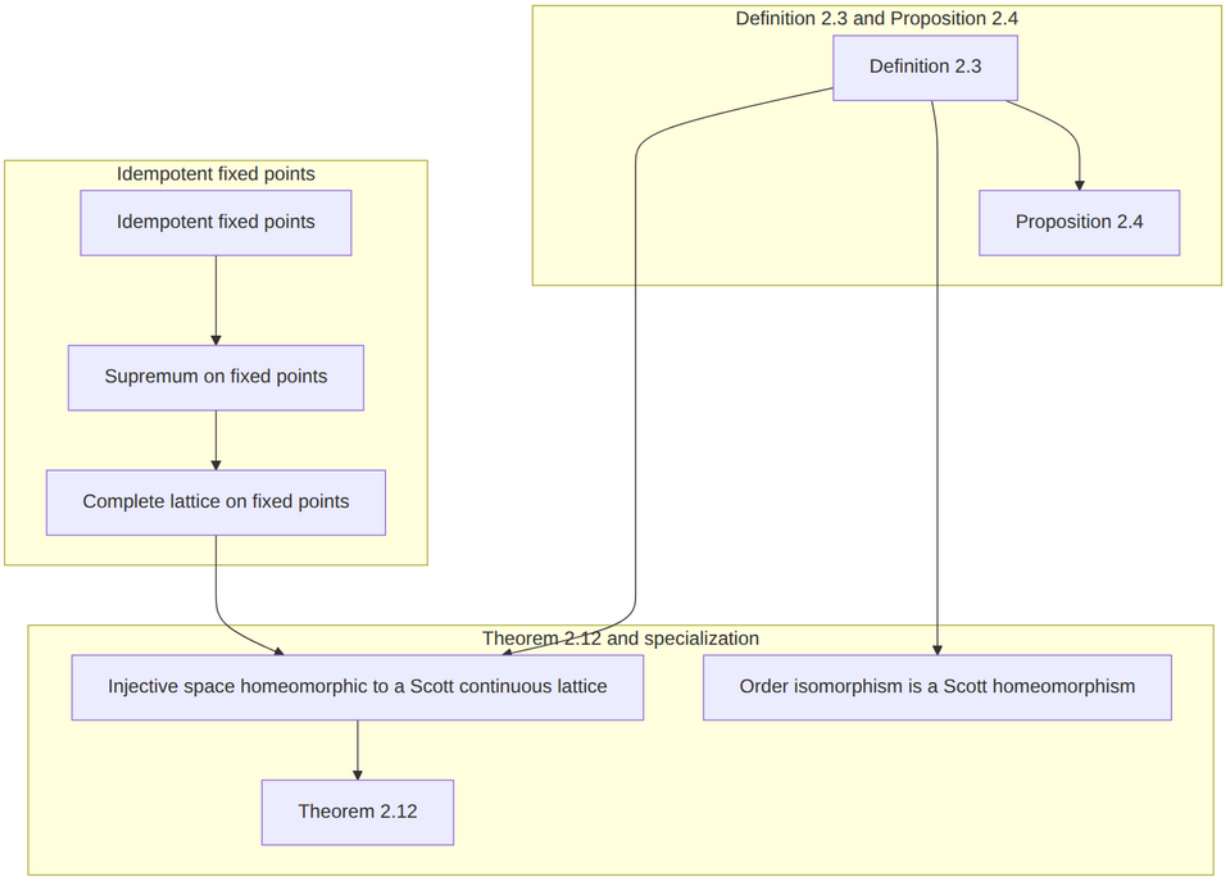

Figure 9: Continuous lattice ✓.

Definition 2.3: Continuous lattice **2.3 Definition.** A *continuous lattice* is a complete lattice D in which for every $y \in D$ we have:

$$y = \bigsqcup \{x \in D : x \ll y\}.$$

On a complete lattice D, the library records this as the typeclass **`ContinuousLattice`**: for every y, the set $\{x : x \ll y\}$ has least upper bound y. Equivalently **`sSup_wayBelow`**: $\sup\{x : x \ll y\} = y$. The way-below relation is **`WayBelow`** / $\ll$; see the Way-below relation note.

Supporting lemmas live in namespace **`ContinuousLattice`** in `ContinuousLattice.lean`. (One interpolation lemma is also exported as **`WayBelow.interpolate`** because it is stated purely in terms of $\ll$, but its proof uses **`ContinuousLattice`**.)

Lemma (`ContinuousLattice.exists_wayBelow_subset`). If D is a continuous lattice, U is Scott-open, and $z \in U$, then there exists $a \ll z$ such that $\{w : a \ll w\} \subseteq U$.

Proof. $\{x : x \ll z\}$ is directed (`WayBelow.directedOn`), has supremum z (`sSup_wayBelow`), and meets U by Scott-openness; any witness a in the intersection works, using that U is an upset. □

Lemma (`ContinuousLattice.exists_wayBelow_Ici_subset`). Under the same hypotheses, there is $a \ll z$ with $\uparrow a \subseteq U$.

Proof. As above, with $\uparrow a$ in place of $\{w : a \ll w\}$. □

Lemma (`ContinuousLattice.orderIso`). If $e : A \to B$ is an order isomorphism and B is a continuous lattice, then so is A (way-below pulls back along e^{-1} via **`WayBelow.map_orderIso`**).

Lemma (`ContinuousLattice.isContinuousLattice_iff_isLUB_sInf_nhds`). D is a continuous lattice iff for every $y \in D$, the set of infima $\inf U$ over Scott-open $U \ni y$ has least upper bound y.

Proof. ($\Rightarrow$) Each $\inf U \ll y$ (`WayBelow.sInf`); the lub of those infs is at most y; **`out`** gives equality. ($\Leftarrow$) Every $x \ll y$ lies in some Scott-open U with $y \in U$, hence $x \le \inf U$; the lub of the infs bounds all way-below elements below y, so **`out`** holds. □

Lemma (`WayBelow.interpolate`). If D is a continuous lattice and $a \ll c$, then there exists b with $a \ll b \ll c$.

Proof. The set $M = \{m : \exists x,\ m \ll x \ll c\}$ is directed; c is its supremum by **`sSup_wayBelow`**; apply **`WayBelow.sSup_iff`**. □

Proposition 2.4 (equivalent formulations via $\inf U \ll y$ and limits) is Scott's discussion after 2.3; the **`isContinuousLattice_iff_isLUB_sInf_nhds`** lemma is the Scott-open inf characterization used in the library.

Proposition 2.4 **2.4 Proposition.** A complete lattice D is continuous iff for every $y \in D$ we have:

$$y = \bigsqcup \{ \sqcap U : y \in U \},$$

where U ranges over the open subsets of D.

Proof: Suppose D is continuous. If $y \in D$ and $x \ll y$, then let $U = \{\mathrm{Int} z : x \sqsubseteq z\}$, an open set. Now $y \in U$ by definition, and $\{U \subseteq z : x \sqsubseteq z\}$. Thus,

$$x \sqsubseteq \sqcap U \sqsubseteq y.$$

It easily follows by lattice theory that the equation of 2.3 implies that of 2.4.

In the converse direction we have only to note that if U is open and $y \in U$, then $\sqcap U \ll y$. The implication from 2.4 to 2.3 results at once. □

Limits and convergence What is the idea of this definition? A continuous lattice is more special than a complete lattice: not only are lubs to be limits but every element must be a limit from below. This rather rough remark can be made more precise. In any complete lattice D define the *principal limit* of a net $x : I \to D$ by the formula:

$$\lim\langle x_i : i \in I\rangle = \bigsqcup\{\sqcap x_j : j \geq i : i \in I\}.$$

Then specify that x converges to $y \in D$ iff

$$y \sqsubseteq \lim\langle\{x_i : i \in I\rangle\}.$$

Having a notion of convergence, we can then say that $U \subseteq D$ is open iff every net converging to an element of U is eventually in U. This gives nothing more than what we have called the induced topology above, as is easily checked. But now being in possession of a topology, we can redefine convergence in the usual way. Question: when do the two notions of convergence agree? Answer: if and only if D is a continuous lattice.

For obviously by construction the limit definition of convergence implies the topological. Now if D is a continuous lattice and x converges to y topologically, consider an open $U \subseteq D$ with $y \in U$. For some $i \in I$ we shall have $x_j \in U$ for all $j \geq i$. Therefore

$$\sqcap U \sqsubseteq \{\sqcap x_j : j \geq i \sqsubseteq \lim\langle x_i : i \in I\rangle\}.$$

From the formula of 2.4 it at once follows that $y \sqsubseteq \lim\langle\{x_i : i \in I\rangle\}$. Thus, in continuous lattices, we have shown that the two notions of convergence are the same.

Finally, suppose that the two notions coincide for a complete lattice D. Define a directed set $I = (U, z) : y, z \in U$, where z ranges over D and U over open subsets of D. This set is directed by the relation: $(U, z) \leq (V, w)$ iff $U \supseteq V$. Let $x : I \to D$ be given by: $x(U, z) = z$. Then x is a net converging to y topologically. But

$$\lim\langle x_i : i \in I\rangle = \bigsqcup\{\sqcap U : y \in U\}.$$

In this way we see that the assumption about the two styles of convergence implies that D is a continuous lattice in view of 2.4.

In T_0-spaces continuous functions are always monotonic (i.e. $\sqsubseteq$-preserving). For continuous lattices, by virtue of the remarks we have just made about limits, we can define the continuity of $f : D \to D'$ to mean that

$$f(\lim\langle\{x_i : i \in I\rangle) \sqsubseteq \lim'\langle f(x_i) : i \in I\rangle\}$$

for all nets $x : I \to D$. This is all very fine, but general limits are messy to work with; we shall find it easier to state results in terms of lubs as in 2.5–2.7 below.

Before going any deeper, however, we should clear up another point about topologies. Suppose that D is any T_0-space which becomes a complete lattice under its induced partial ordering. Then it is evident from our definitions that every set open in the given topology is also open in the topology induced from the lattice structure. Question: when do the two topologies agree? Answer: a sufficient condition is that the equation:

$$y = \bigsqcup\{\sqcap U : y \in U\}$$

hold for all $y \in D$, where U ranges over the given open sets. Because in that case if V is open in the lattice sense and $y \in V$, then $\sqcap U \in V$ for some set U, open in the given sense, where $y \in U$. But $U \subseteq V$ follows, and so V is a union of given open sets and is itself open in the given topology. Of course this equation implies that D is a continuous lattice by virtue of 2.4. Notice that by the same token the sets of the form $\{y \in D : x \ll y\}$ will form a basis for the open sets of a continuous lattice.

hold for all $y \in D$, where U ranges over the given open sets. Because in that case if V is open in the lattice sense and $y \in V$, then $\sqcap U \in V$ for some set U, open in the given sense, where $y \in U$. But $U \subseteq V$ follows, and so V is a union of given open sets and is itself open in the given topology. Of course this equation implies that D is a continuous lattice by virtue of 2.4. Notice that by the same token the sets of the form $\{y \in D : x \ll y\}$ will form a basis for the open sets of a continuous lattice.

Idempotent fixed points On a complete lattice L, write $e : L \to L$ for an endomap. We say e is **idempotent** when $e \circ e = e$ (equivalently $e(ex) = ex$ for all x). An element $x \in L$ is a **fixed point** of e when $e(x) = x$.

Scott's discussion after Theorem 2.12 treats a retraction $j : \mathcal{P}I \to \mathcal{P}I$ as idempotent and identifies its range with $\{X : j(X) = X\}$. The proof of Theorem 2.12 uses the same fixed-point subtype for the idempotent $e = s \circ r$ built from an injective-space retraction into a Sierpiński power.

Definition (`IdempotentFixedPoint`). For $e : L \to L$ on a complete lattice L, **`IdempotentFixedPoint e`** is the subtype $\{x \in L \mid ex = x\}$.

`IdempotentFixedPoint.lean`

namespace DomainTheory.ContinuousLattice

variable {L : Type*} [CompleteLattice L]

/-- Fixed points `{x | e x = x}` of an endomap on a complete lattice. -/
abbrev IdempotentFixedPoint (e : L → L) : Type _ := {x : L // e x = x}

end DomainTheory.ContinuousLattice
```

Supremum on fixed points When e is idempotent on a complete lattice L, the fixed-point subtype **`IdempotentFixedPoint e`** needs a join operation: ambient suprema of fixed points need not be fixed, but applying e after taking the supremum lands back in the fixed-point set. The lemmas below live in namespace **`IdempotentFixedPoint.supremumSet`** in `IdempotentFixedPoint/supremumSet.lean`. See Idempotent fixed points for the subtype definition. The **`CompleteLattice`** instance built from this **`SupSet`** is Complete lattice on fixed points.

Definition (`IdempotentFixedPoint.supremumSet`). Given $e(ex) = ex$, the **`SupSet`** instance sends a set S of fixed points to $e(\sup\{\mathrm{val}\, k : k \in S\})$ in L, packaged as a fixed point using idempotence.

Proof. Definition only (`supremumSet` in Lean). □

Theorem (`IdempotentFixedPoint.supremumSet.isLUB`). With **`IdempotentFixedPoint.supremumS`** `sSup S` is a least upper bound of S in the fixed-point order (requires **`Monotone e`**).

Proof. Write $u = e(\sup \operatorname{val} S)$ for the proposed supremum.

Upper bound. If $k \in S$, then $\operatorname{val} k \le \sup \operatorname{val} S$ in L, so $e(\operatorname{val} k) \le u$ by monotonicity; fixedness gives $\operatorname{val} k = e(\operatorname{val} k) \le u$.

Least. If w is an upper bound of S among fixed points, then $\operatorname{val} k \le \operatorname{val} w$ for all $k \in S$, hence $\sup \operatorname{val} S \le \operatorname{val} w$; monotonicity yields $u \le e(\operatorname{val} w) = \operatorname{val} w$. □

Injective space homeomorphic to a Scott continuous lattice This is the **constructive half** of Theorem 2.12 before the biconditional is stated: from injectivity alone (Corollary 1.6, Sierpiński power, idempotent fixed points, Propositions 2.9–2.10) one builds a **continuous lattice** and a **homeomorphism** to it with **Scott** topology. See Idempotent fixed points for the fixed-point subtype used in the proof. The full iff is Theorem 2.12; when a lattice order and topology are already given and specialization equals $\leq$, see Specialization equals the given complete-lattice order on injective T0 spaces.

Theorem (`injective_homeomorph_to_continuousLatticeScott`). If D is an injective T_0 space, then there exist a complete lattice E, a **`ContinuousLattice`** structure on E, and a homeomorphism $D \cong E$ where E carries its **Scott** topology.

Proof. Retract D into a Sierpiński power; form the idempotent $e = s \circ r$; take **`IdempotentFixedPoint e`** with **`completeLattice`**, **`isContinuousLattice`**, and **`scottTopology`**; homeomorph D to the fixed-point set as a subspace. □

Theorem 2.12 **2.12 Theorem.** The injective spaces are exactly the continuous lattices.

This theorem is an immediate consequence of the preceding results: an injective space is a retract of a power of $\mathbb{O}$. But $\mathbb{O}$ is a finite lattice $(\bot \sqsubseteq \top)$, and so the given space is a continuous lattice under its induced topology. On the other hand a continuous lattice is injective. It remains then to prove 2.9–2.11.

The library splits the two directions: Injective space homeomorphic to a Scott continuous lattice (**`injective_homeomorph_to_continuousLatticeScott`**) is the injective $\Rightarrow$ homeomorph-to-Scott-CL step; **`proposition_2_11`** is continuous lattice $\Rightarrow$ injective. When a complete lattice and topology are already on the type and specialization equals $\leq$, Specialization equals the given complete-lattice order on injective T0 spaces refines the constructive direction (**`continuousLattice_scottTopology_of_injective`**).

Theorem (`theorem_2_12`). For a T_0 space D, **`InjectiveSpace D`** iff there exist a complete lattice E, a **`ContinuousLattice`** instance on E, and a homeomorphism $D \cong E$ with E carrying its Scott topology.

Proof. In `theorem_2_12.lean`: the forward implication is **`injective_homeomorph_to_continuousLatticeScott`**; the converse applies **`proposition_2_11`** and **`proposition_1_4`** to a witnessing homeomorphism. □

Specialization equals the given complete-lattice order on injective T0 spaces Theorem 2.12 and Injective space homeomorphic to a Scott continuous lattice show that an injective T_0 space is homeomorphic to **some** Scott continuous lattice. In **inverse limits** (and similar setups) one already has a **complete lattice** and **topology** on the type, and **`SpecializationPreorder`** is known to agree with that lattice's $\leq$. This note is the transfer lemma: promote the existential homeomorphism to **`ContinuousLattice`** and **Scott** for **that** data.

Primary use: Proposition 4.1 and **`scottTopology_eq_induced_pi`**, after injectivity and **`specializationPreorder_iff`** are available on the inverse limit. Scott topology along an order iso is Order isomorphism is a Scott homeomorphism.

Theorem (`continuousLattice_scottTopology_of_injective`). Let A be a complete lattice with topology τ_A. If A is T_0 and injective, and for all $x, y \in A$ we have specialization $x \rightsquigarrow y$ iff $x \leq_A y$, then A is a **`ContinuousLattice`** for $\leq_A$ and τ_A equals the **Scott** topology for $\leq_A$.

Proof. **`injective_homeomorph_to_continuousLatticeScott`** gives E, a Scott **`ContinuousLattice`** on E, and a homeomorphism $h : A \cong E$.

Order iso. **`SpecializationPreorder.scott_iff`**, **`SpecializationPreorder.map`**, and `hspec` show h is an order isomorphism $e : A \cong E$.

Continuous lattice. **`ContinuousLattice.orderIso e`**.

Scott topology. **`orderIsoScottHomeomorph`** (see linked note) identifies Scott on A with the topology induced from Scott on E along e; **`Homeomorph.isInducing`** matches τ_A with the same induced topology along h. □

After Theorem 2.12 Following Theorem 2.12, Scott steps back from the proof to compare two pictures of the same equivalence.

The **lattice approach** to injective spaces gives a completely "internal" characterization: the types are complete lattices; **way-below** ($\ll$, Definition 2.3) is defined lattice-theoretically by

$$x \ll y \quad \text{iff} \quad \text{whenever } y \sqsubseteq \bigsqcup Z \text{ and } Z \subseteq D \text{ is directed,}$$

then $x \sqsubseteq z$ for some $z \in Z$; and every $y \in D$ satisfies

$$y = \bigsqcup \{x \in D : x \ll y\}.$$

That makes D a continuous lattice with the sets $\{y \in D : x \ll y\}$ as a basis for the topology. Such T_0-spaces are injective, every injective space arises this way, and the lattice structure is uniquely determined by the topology. Furthermore, as in the proof of 2.11, injectivity can be exhibited by an explicit extension formula.

The **retract approach** should also be considered. Cartesian powers $\mathbb{O}^I$ are simple: as lattices they are Boolean algebras of all subsets of I. The topology has as a basis the classes of sets containing given finite sets (the *weak topology*, cf. [17]). A continuous function

$$j : \mathcal{P}I \to \mathcal{P}I$$

is one of "finite character", so

$$j(X) = \bigcup \{j(F) : F \subseteq X\}$$

where $X \subseteq I$ and F ranges over *finite* sets. Such j is a *retraction* iff it is *idempotent* ($j \circ j = j$), so the range is the set of fixed points. As we have seen in Idempotent fixed points,

$$D = \{X \in \mathcal{P}I : j(X) = X\}$$

is a continuous lattice (under $\subseteq$ here), and *every* continuous lattice is isomorphic to one obtained this way. This is a representation theorem, but Scott warns it is not very helpful for proofs.

Finally, any space (any finite family of spaces $X, Y, \ldots$) embeds as a *subspace* of some continuous lattice D. Since D is injective, every continuous $f : X \to Y$ extends to some $\bar{f} : D \to D$; maps $D \to D$ therefore encode continuous maps on all subspaces—motivation for Function spaces.

Proposition 2.5 **2.5 Proposition.** *If D and D' are complete lattices with their induced topologies, then a function $f : D \to D'$ is continuous iff for all directed subsets $S \subseteq D$:*

$$f(\bigsqcup S) = \bigsqcup \{f(x) : x \in S\}.$$

Proof: If $f : D \to D'$ is continuous, the equation follows from the definition of continuous function and the fact that lubs are limits. Assume then that the equation holds for all directed sets S. Let $U' \subseteq D'$ be open in D' and let

$$U = \{x \in D : f(x) \in U'\}.$$

We must show that U is open in D. Note first that if $x \sqsubseteq y$, then $S = x, y$ is directed; hence,

$$f(x \sqcup y) = f(y) = f(x) \sqcup f(y),$$

so $f(x) \sqsubseteq f(y)$. Thus f is monotonic and so U satisfies condition (i). That U satisfies condition (ii) follows at once from the above equation. □

Proposition 2.6 **2.6 Proposition.** *With functions from complete lattices to complete lattices, a function of several variables is continuous in the variables jointly iff it is continuous in the variables separately.*

Proof: It will be sufficient to discuss functions of two variables. The product $D \times D'$ of two complete lattices is a complete lattice, and it is easy to check that the induced topology is the product topology. Since projection is continuous, joint continuity implies separate continuity. To check the converse suppose that

$$f : D \times D' \to D''$$

is a map where the separate continuity holds as follows:

$$f(\bigsqcup S, y) = \bigsqcup f(x, y) : x \in S$$

and

$$f(x, \bigsqcup S') = \bigsqcup \{f(x, y) : y \in S'\}$$

where $S \subseteq D$ and $S' \subseteq D'$ are directed and $x \in D$ and $y \in D'$. Let now

$$S^* \subseteq D \times D'$$

be directed in the product. The projection of S^* to D and of S^* to D' produces directed subsets $S \subseteq D$ and $S' \subseteq D'$. Note that

$$\bigsqcup S^* = (\bigsqcup S, \bigsqcup S').$$

Thus by assumption

$$f(\bigsqcup S^*) = \bigsqcup \{f(x,y) : x \in S, y \in S'\}.$$

But since S^* is directed, $x \in S$ and $y \in S'$ implies $x \sqsubseteq u$ and $y \sqsubseteq v$ for $(u,v) \in S^*$. Thus by monotonicity of f we can show

$$f(\bigsqcup S^*) = \bigsqcup \{f(u,v) : (u,v) \in S^*\}$$

and that gives the joint continuity. □

One of the justifications (by euphony at least) of the term *continuous lattice* is the fact that such spaces allow for so many continuous functions. One indication of this is the result:

Proposition 2.7 **2.7 Proposition.** *In a continuous lattice D the finitary lattice operations $\sqcup$ and $\sqcap$ are continuous.*

Proof: It is trivial to show that $\sqcup$ is continuous in every complete lattice; this is not so for $\sqcap$. In view of 2.6 we need only show

$$x \sqcap \bigsqcup S = \bigsqcup \{x \sqcap y : y \in S\}$$

for every directed $S \subseteq D$. In fact it is enough to show

$$x \sqcap \bigsqcup S \sqsubseteq \bigsqcup \{x \sqcap y : y \in S\}$$

because the opposite inequality is valid in all complete lattices. In view of the fact that D is continuous, it is enough to show that

$$t \ll x \sqcap \bigsqcup S \text{ implies } t \sqsubseteq \bigsqcup \{x \sqcap y : y \in S\}.$$

So assume $t \ll x \sqcap \bigsqcup S$. Then $t \sqsubseteq x \sqcap \bigsqcup S \sqsubseteq x$. Also $t \ll \bigsqcup S$ because $x \sqcap \bigsqcup S \sqsubseteq \bigsqcup S$. Thus $t \ll y$ for some $y \in S$ since the set

$$\{z \in D : t \ll z\}$$

is open. But then $t \sqsubseteq y$, and so $t \sqsubseteq x \sqcap y$, and the result follows. □

It is now time to provide some examples of continuous lattices.

2.3.7 Proposition 2.10 ✓

2.10 Proposition. A retract of a continuous lattice is a continuous lattice with the subspace topology agreeing with the induced topology.

It would seem that the continuous lattices are starting to sound suspiciously like the injective spaces. Indeed, if we can prove the following, the circle will be complete.

2.3.9 Proof of 2.9 ✓

Proof of 2.9

Let D_i for $i \in I$ be a system of continuous lattices. The product

$$D^* = \prod_{i \in I} D_i$$

is a complete lattice in the usual way and has its induced topology. Suppose $y \in D^*$ and let $i \in I$. Then $y_i \in D_i$. Since D_i is a continuous lattice

$$y_i = \bigsqcup \{x \in D_i : x \ll y_i\}.$$

For $x \in D_i$, let $[x]^i \in D^*$ be defined by:

$$[x]^i_j = \begin{cases} x & \text{if } i = j, \\ \bot & \text{if } i \neq j. \end{cases}$$

Note that since D_i is continuous we have:

$$[y_i]^i = \bigsqcup \{[x]^i : x \ll y_i\},$$

and

$$y = \bigsqcup \{[y_i]^i : i \in I\}.$$

It follows that

$$y = \bigsqcup \bigcap \{ z : z_i \in U \text{ for all } i \in I,\ y_i \in U \},$$

where i ranges over I and U over the open subsets of D_i, because

$$[x]^i \sqsubseteq \bigcap \{ z : z_i \in U \}, \quad \text{where } U = \{ u \in D_i : x \ll u \}.$$

But the sets $\{ z : z_i \in U \}$ are open in the product sense, and so

$$y = \bigsqcup \bigcap \{ U : y \in U \},$$

where U ranges now over the open subsets of the product topology on D^*. By the remark following 2.4 we conclude that D^* is continuous with the lattice-induced topology being the product topology. □

2.3.10 Continuous lattice retraction ✓

Definition. For complete lattices D and D', a **continuous lattice retraction** of D into D' is a pair of Scott-continuous maps $i : D \to D'$ and $j : D' \to D$ such that $j \circ i = \mathrm{id}_D$. The library packages this as **`ContinuousLatticeRetraction D D'`** with **`incl`** (i), **`retr`** (j), and **`retr_incl`**.

In the namespace **`ContinuousLatticeRetraction`** we have

Theorem (`incl_preservesDirectedSup`). *The inclusion i preserves directed suprema: for every directed set $S \subseteq D$,*

$$i(\bigsqcup S) = \bigsqcup i(S).$$

Proof. i is Scott-continuous as a **`ScottMap`**, and that is exactly preservation of directed suprema. □

Theorem (`image_retr_wayBelow_directed`). *Fix $d \in D$. The set*

$$J_d := \{\, j(x') \mid x' \ll i(d) \,\}$$

is directed in D.

Proof. Given $j(a)$ and $j(b)$ with $a, b \ll i(d)$, the way-below relation is closed under finite suprema, so $a \sqcup b \ll i(d)$; monotonicity of j then yields an upper bound $j(a \sqcup b)$ in J_d below both elements. □

Theorem (`image_retr_wayBelow_nonempty`). *The set J_d is nonempty.*

Proof. $\bot \ll i(d)$ and $j(\bot) \in J_d$. □

Theorem (`sSup_image_retr_wayBelow`). *If D is a continuous lattice, then for every $d \in D$,*

$$\bigsqcup J_d = d.$$

Proof. The set $\{\, x' \mid x' \ll i(d) \,\}$ is directed and nonempty, so j preserves its supremum. On that set the continuous-lattice identity $i(d) = \bigsqcup\{x' \mid x' \ll i(d)\}$ and $j \circ i = \mathrm{id}_D$ give $\bigsqcup J_d = j(i(d)) = d$. □

Theorem (`retr_wayBelow_of_wayBelow_incl`). *If $x' \ll i(d)$ in D', then $j(x') \ll d$ in D.*

Proof. By the definition of $x' \ll i(d)$ there is a Scott-open $U' \subseteq D'$ with $i(d) \in U'$ and $U' \subseteq\!\uparrow x'$. The preimage $i^{-1}(U')$ is Scott-open because i preserves directed suprema; it contains d and every $z \in i^{-1}(U')$ satisfies $x' \le i(z)$, hence $j(x') \le j(i(z)) = z$. So $j(x') \ll d$. □

Definition (`ambientSSup`). *For $S \subseteq D$, the ambient supremum is $i(\bigsqcup S)$ in D' (the join taken in D, then mapped forward).*

Theorem (`retr_ambientSSup_eq_sSup`). *If $S \subseteq D$ is nonempty and directed, then*

$$j\big(i(\bigsqcup S)\big) = \bigsqcup S.$$

Proof. The image $i(S)$ is directed, so $i(\bigsqcup S) = \bigsqcup i(S)$ and j preserves that directed supremum. Pulling back along $j \circ i = \mathrm{id}_D$ on S yields the claim. □

2.3.11 Converse retraction ✓

Definition. Let D and D' be complete lattices and let $i : D \to D'$ be Scott-continuous. The **converse retraction** along i is the map $j : D' \to D$ given by

$$j(x') = \bigsqcup \{x \in D \mid i(x) \le x'\}.$$

The library name is **`ConverseRetraction.ConverseRetraction i`** (`ConverseRetraction.lean`).

In the namespace **`ConverseRetraction`** we have

Theorem (`mono`). *The map $x' \mapsto j(x')$ is monotone.*

Proof. If $a' \le b'$, every x with $i(x) \le a'$ also satisfies $i(x) \le b'$, so the defining set for $j(a')$ is contained in that for $j(b')$ and $j(a') \le j(b')$. $\square$

Theorem (`preservesDirectedSup`). *Suppose $i(\bigsqcup S) = \bigsqcup i(S)$ for every $S \subseteq D$, that $x \ll y$ implies $i(x) \ll i(y)$, and that D is a continuous lattice. Then j preserves directed suprema.*

Proof. For directed $S' \subseteq D'$, one inequality follows from monotonicity: $j(\bigsqcup S')$ is an upper bound of $j(S')$. For the reverse, any x with $i(x) \le \bigsqcup S'$ is way-below that supremum in D', hence way-below some

$x' \in S'$ by directedness; then $x \le j(x') \le \bigsqcup j(S')$. Continuity of D rewrites $j(\bigsqcup S')$ as a supremum of such x. □

Theorem (`incl_converseRetr_le`). *If $i(\bigsqcup S) = \bigsqcup i(S)$ for all S, then for every $x' \in D'$, $i(j(x')) \le x'$.*

Proof. Each element of $\{x \mid i(x) \le x'\}$ maps under i into $\uparrow x'$; take the supremum. □

Theorem (`converseRetr_incl`). *Under the same $\bigsqcup$-preservation, if i is injective, then $j(i(y)) = y$.*

Proof. The set $\{x \mid i(x) \le i(y)\}$ is exactly $\downarrow y$; its supremum is y. □

2.3.12 Continuous lattice projection ✓

Definition. A **continuous lattice projection** is a continuous lattice retraction $i : D \to D'$, $j : D' \to D$ with $j \circ i = \mathrm{id}_D$ that also satisfies $i(j(x')) \le x'$ for all $x' \in D'$. The library extends **`ContinuousLatticeRetraction`** to **`ContinuousLatticeProjection D D'`** with the field **`incl_retr_le`**. Scott's Definition 3.6 uses this data for function-space extensions; Proposition 2.10 and later §3 results build on it.

In the namespace **`ContinuousLatticeProjection`** we have

Theorem (`retr_bot`). *For a projection P, $j(\bot_{D'}) = \bot_D$.*

Proof. $\bot_{D'} \le i(\bot_D)$, so $j(\bot_{D'}) \le j(i(\bot_D)) = \bot_D$; the reverse is $\bot_D \le j(\bot_{D'})$. □

Theorem (`incl_bot`). $i(\bot_D) = \bot_{D'}$.

Proof. By **`incl_retr_le`**, $i(j(\bot_{D'})) \le \bot_{D'}$; with **`retr_bot`**, $i(\bot_D) \le \bot_{D'}$. □

Theorem (`retr_eq_sSup`). *For every $x' \in D'$,*

$$j(x') = \bigsqcup \{\, x \in D \mid i(x) \le x' \,\}.$$

Proof. **`incl_retr_le`** gives $i(j(x')) \le x'$, so $j(x')$ lies in the set and is below its supremum. Any x with $i(x) \le x'$ satisfies $x = j(i(x)) \le j(x')$ by monotonicity of j. □

Theorem (`incl_wayBelow`). *If D is a continuous lattice and $x \ll y$ in D, then $i(x) \ll i(y)$ in D'.*

Proof. Rewrite y as a directed supremum of way-below elements in D' below $i(y)$, pull back along j, and use $x \ll y$ with **`incl_retr_le`** on the approximants. □

Theorem (`incl_injective`). *i is injective.*

Proof. From $i(x) = i(y)$ apply j and **`retr_incl`**. □

Theorem (`incl_sup`). $i(x \sqcup y) = i(x) \sqcup i(y)$.

Proof. Monotonicity gives one inequality; the other uses $x, y \le j(i(x) \sqcup i(y))$ from **`retr_incl`**, then **`incl_retr_le`** at $i(x) \sqcup i(y)$. □

Theorem (`incl_finset_sup`). *For finite $T \subseteq D$, $i(\bigsqcup T) = \bigsqcup i(T)$.*

Proof. Induction on T using **`incl_sup`** and **`incl_bot`**. □

Definition (`finsetSupOf`). *For $S \subseteq D$, let **`finsetSupOf S`** be the set of finite suprema $\bigsqcup T$ with $T \subseteq_{\text{fin}} S$.*

Theorem (`directedOn_finsetSupOf`). *`finsetSupOf S` is directed.*

Proof. Given two finite suprema from $T_1, T_2 \subseteq S$, their common upper bound is the supremum of $T_1 \cup T_2$. □

Theorem (`mem_finsetSupOf_of_mem`). *If $x \in S$, then $x \in \mathrm{finsetSupOf}\ S$.*

Proof. Take the singleton finset $\{x\}$. □

Theorem (`sSup_le_finsetSupOf`). $\bigsqcup \mathrm{finsetSupOf}\ S \le \bigsqcup S$.

Proof. Each finite supremum in **`finsetSupOf S`** is below $\bigsqcup S$. □

Theorem (`le_sSup_finsetSupOf`). $\bigsqcup S \le \bigsqcup \mathrm{finsetSupOf}\ S$.

Proof. Every $x \in S$ appears in **`finsetSupOf S`**. □

Theorem (`sSup_finsetSupOf`). $\bigsqcup S = \bigsqcup \mathrm{finsetSupOf}\ S$.

Proof. Antisymmetry of the two preceding inequalities. □

Theorem (`incl_sSup`). $i(\bigsqcup S) = \bigsqcup i(S)$.

Proof. Empty S uses **`incl_bot`**. Otherwise replace $\bigsqcup S$ by finite suprema via **`sSup_finsetSupOf`**, use directedness and **`incl_finset_sup`**, and compare with the image under i. □

Theorem (`incl_sup_of_preservesSSup`). *If $i(\bigsqcup S) = \bigsqcup i(S)$ for all S, then $i(x \sqcup y) = i(x) \sqcup i(y)$.*

Proof. Write $x \sqcup y$ as $\bigsqcup\{x, y\}$. □

Theorem (`incl_mono_of_preservesSSup`). *Under the same hypothesis, i is monotone.*

Proof. If $x \le y$, apply **`incl_sup_of_preservesSSup`** and read off $i(x) \le i(y)$. □

Theorem (`le_of_incl_le`). *If i is injective and preserves suprema of sets, then $i(x) \le i(y)$ implies $x \le y$.*

Proof. $i(x \sqcup y) = i(y)$ forces $x \sqcup y = y$ by injectivity. □

Building a projection from an inclusion i and the converse retraction is in Converse projection.

2.3.13 Converse projection ✓

When $i : D \to D'$ is injective, preserves suprema of sets, preserves way-below, and D is a continuous lattice, Scott builds a **continuous lattice projection** from i and the converse retraction (see Converse retraction). The library name is **`ConverseProjection i`** (`ConverseProjection.lean`).

Definition (`ConverseProjection`). *Under the hypotheses above, **`ConverseProjection i`** is the **`ContinuousLatticeProjection`** with inclusion i and retraction **`ConverseRetraction.ConverseRetrac i`**.

Proof. **`ConverseRetraction.converseRetr_incl`** and **`ConverseRetraction.incl_converseRetr_le`** supply **`retr_incl`** and **`incl_retr_le`**; Scott continuity comes from **`ConverseRetraction.`** □

2.3.14 Proof of 2.10 ✓

Proof of 2.10

Let D' be a continuous lattice and let $D \subseteq D'$ be a subspace which is a retract. We have for a suitable $j : D' \to D$,

$$D = \{x \in D' : j(x) = x\},$$

where of course j is continuous.

First a note of warning: though D is a subspace it is not a sublattice; that is, the partial ordering on D is the restriction of that of D', but the lubs of D are not those of D'. We shall have to distinguish operations by adding a prime ($'$) for those of D'.

Suppose $x, y \in D$. Let $z' = x \sqcup y \in D'$ (join taken in D') and define $z = j(z') \in D$. Now $x \sqsubseteq z'$ and $y \sqsubseteq z'$, and j is monotonic, so $x \sqsubseteq z$ and $y \sqsubseteq z$. Suppose $x \sqsubseteq w$ and $y \sqsubseteq w$ with $w \in D$. Then in D' we have $x \sqcup y \sqsubseteq w$; so $z \sqsubseteq w$ also. Hence we have shown that $z = x \sqcup y$ in D.

To show that D has a least element $\bot$ (which may be larger than the $\bot' \in D'$), we need a well-known lemma about monotonic functions: Every monotonic function on a complete lattice into itself has a least fixed point. (Cf. [18, p. 115].) In our case j is monotonic and

$$\bot = \sqcap \{x \in D' : j(x) \sqsubseteq x\}$$

is the desired element in D.

Thus D is at least a semilattice with $\bot$ and $\sqcup$. To show that D is a lattice we need to show that every directed $S \subseteq D$ has a lub in D. Now we know ($S' = S$, join taken in the ambient lattice D'):

$$\bigsqcup S' \in D',$$

and this is a limit of a monotone net. So by 2.1, and the continuity of j:

$$j(\bigsqcup S') = \bigsqcup\{j(x) : x \in S\} \quad = \bigsqcup S$$

in D. In this way we now know that D is a complete lattice. We must still show that D is continuous.

Suppose $y \in D$. In D' we can write:

$$y = \bigsqcup\{x \in D' : x \ll y'\}$$

and this is the limit of a monotone net. Thus

$$j(y) = y = \bigsqcup j(x) : x \ll y, x \in D',$$

where the lub is taken in D. Note that the sets

$$U = \{z \in D : x \ll z\}$$

are open in D for each $x \in D'$. Note too that if $z \in U$, then $x \sqsubseteq z$ and so $j(x) \sqsubseteq j(z) = z$. This means that

$$j(x) \sqsubseteq \sqcap U$$

in D. We can then write in D:

$$y = \bigsqcup\{\sqcap U : y \in U\}$$

where U ranges over the open subsets of D, and so the lattice is continuous by 2.4. Inasmuch as the open sets U just used were open in the subspace topology, it follows by the remark after 2.4 that the subspace and the lattice-induced topologies coincide. □

2.3.15 Proof of 2.11 ✓

Proof of 2.11: Let D be a continuous lattice with its induced topology, and let $X \subseteq Y$ be two T_0-spaces in the subspace relation. Suppose

$$f : X \to D$$

is continuous. Define

$$\bar{f} : Y \to D$$

by the formula:

$$\bar{f}(y) = \bigsqcup \{ \sqcap \{ f(x) : x \in X \cap U \} : y \in U \},$$

where U ranges over the open subsets of Y. We need to show that $\bar{f}$ extends f and that it is continuous.

First, the continuity: Suppose that $d \in D$ and $d \ll \bar{f}(y)$; that is, $\bar{f}(y)$ belongs to a typical basic open subset of D. Since D is continuous, we can also find

$$d \ll d' \ll \bar{f}(y)$$

with $d' \in D$. From the definition of $\bar{f}$ it follows that

$$d' \sqsubseteq \sqcap \{ f(x) : x \in X \cap U \}$$

for some open $U \subseteq Y$ with $y \in U$. Thus

$$d' \sqsubseteq \bar{f}(y')$$

for all $y' \in U$ by virtue of the definition of $\bar{f}$. Since $d \ll d'$, we have also

$$d \ll \bar{f}(y')$$

for all $y' \in U$; in other words, the inverse image of the open subset of D determined by d under $\bar{f}$ is indeed open in Y, and $\bar{f}$ is thus continuous.

Next, the extension property: Note that the relationship

$$\bar{f}(x') \sqsubseteq f(x')$$

for all $x' \in X$ comes directly out of the definition of $\bar{f}$. For the converse, suppose $d \ll f(x')$ where $d \in D$. By assumption $f : X \to D$ is continuous, so

$$d \ll f(x'')$$

for all $x'' \in X \cap U$ where U is a suitable open subset of Y with $x' \in U$. In particular we have:

$$d \sqsubseteq \sqcap \{ f(x'') : x'' \in X \cap U \},$$

and so $d \sqsubseteq \bar{f}(x')$. Since $d \ll f(x')$ always implies $d \sqsubseteq \bar{f}(x')$, we see that $f(x') \sqsubseteq \bar{f}(x')$ follows by the continuity of D, and the proof is complete. □

2.4 Function spaces ✓

We recall the standard definition and introduce our notation for function spaces.

Figure 11: Function spaces ✓.

2.4.1 Induced pi topology on $C(X, Y)$ ✓

Library packaging for the product (pointwise) topology on continuous maps between T_0-spaces, before Definition 3.1 specializes the eval subbase on **`C(X, Y)`**.

For T_0-spaces X and Y, Definition 3.1 identifies $[X \to Y]$ with **`C(X, Y)`** and equips it with the *product topology* (topology of pointwise convergence). Mathlib already carries the product topology on Y^X; restricting to continuous maps gives the subspace topology induced along the inclusion **`C(X, Y)`** $\hookrightarrow$ **`X → Y`**.

Definition (`continuousMapInducedPiTopology`). **`continuousMapInducedPiTopology X Y`** is that induced topology on **`C(X, Y)`**: the pi (product) topology on Y^X, pulled back along `(f : C(X, Y)) ↦ (f : X → Y)`.

This definition is the generic T_0 packaging used before lattices enter the story. On **`ScottFunctionTopology.lean`**, **`scottFunctionTopology X Y`** is built from the eval subbase of Definition 3.1; **`scottFunctionTopology.eq_induced_pi`** proves **`scottFunctionTopology X Y = continuousMapInducedPiTopology X Y`**, so Scott's subbase description and the product topology coincide on **`C(X, Y)`**.

end DomainTheory.ContinuousLattice
```

2.4.2 Definition 3.1: Function space ✓

3.1 Definition. For T_0-spaces X and Y we let $[X \to Y]$ be the *space of all continuous functions* $f : X \to Y$ endowed with the product topology, sometimes called the topology of pointwise convergence. This topology has as a subbase sets of the form:

$$\{f : f(x) \in U\}$$

where $x \in X$ and $U \subseteq Y$ is open.

The pointwise aspect of the topology is immediately apparent in the partial ordering.

For T_0-spaces X and Y, the library identifies $[X \to Y]$ with **`C(X, Y).scottFunctionTopology.evalSubbasi`**
`X Y` is the family of subbasic sets $\{ f \in C(X,Y) \mid f(x) \in U \}$ with $x \in X$ and $U \subseteq Y$ open. **`scottFunctionTopology X Y`** is the topology generated from that subbase.

The lemmas in namespace **`scottFunctionTopology`** justify this packaging:

Lemma (`subbasis_isOpen`). For open $U \subseteq Y$ and $x \in X$, the subbasic set $\{ f \mid f(x) \in U \}$ is open in `scottFunctionTopology X Y`.

Lemma (`subbasis_isOpen_scott`). When D and D' are complete lattices and $U \subseteq D'$ is open in **`scottTopologicalSpace`**, the same subbasic set $\{ f \in C(D, D') \mid f(x) \in U \}$ is open in **`scottFunctionTopology D D'`** with both domain and codomain carrying the Scott topology (used in Corollary 3.4).

Theorem (`eq_induced_pi`). `scottFunctionTopology X Y` is the product topology on Y^X (pointwise convergence), induced along the inclusion of continuous maps into all maps $X \to Y$.

Lemma (`specializationPreorder_generateOpen`). If $f(x) \sqsubseteq g(x)$ for every $x \in X$, and $V \subseteq C(X,Y)$ is open in the topology generated from the eval subbase with $f \in V$, then $g \in V$.

Theorem (`specializationPreorder`). With the specialization preorder from `scottFunctionTopology X Y`, $f \sqsubseteq g$ iff $f(x) \sqsubseteq g(x)$ for all $x \in X$ — the pointwise specialization order on the function space (the content of Proposition 3.2, proved there as `proposition_3_2` via this lemma).

2.4.3 Elements of $[D \to D']$ ✓

For continuous lattices D and D', Scott's §3 notation $[D \to D']$ is the set of maps $f : D \to D'$ that are continuous for the Scott topologies (equivalently, Scott-continuous in the sense of §2). The library names that carrier **`ScottMap D D'`**: a subtype of $D \to D'$ carrying a proof of continuity for **`scottTopologicalSpace`** on domain and codomain.

`ScottMap.lean` is **self-contained**: it does not import or mention **`stepFun`** or **`stepMap`**. Step functions for Theorem 3.3 are in Step function (pointwise) and Step map $\overrightarrow{e}[e, e']$. Scott's projection space J_D (**`ProjectionSpace`**, Definition 3.11) and sup-closure (Proposition 3.12) are in Definition 3.11: Projection space. Retractions between map spaces (**`ScottMap.retraction`**) are in Retractions and extensions. **`FunctionSpace.retraction`** and **`FunctionSpace.projection`** are in Function-space retraction and projection; Proposition 3.7 is the paper statement. Projections on map spaces and **`ScottMap.conMinContinuousLatticeProjection`** are in Definition 3.6; **`con`** / **`min`** appear in Proposition 3.13.

Namespace **`ScottMap`** collects the library tools on that carrier:

Instance (`CoeFun`). A Scott map coerces to its underlying function $D \to D'$.

Lemma (`ext`). Two Scott maps agree if they agree at every argument.

Definition (`const`). The constant Scott map at $c \in D'$; **`const_apply`** reads off c at each x.

Definition (`con`). Scott's $\mathrm{con} : D \to [D \to D]$: at x the constant endo-map $\mathrm{con}(x) = \mathrm{const}\, x$.

Definition (`min`). Scott's $\mathrm{min} : [D \to D] \to D$: **`min f = f(⊥)`** on the coercion.

Definition (`toOrderHom`). **`OrderHom`** view of $f \in [D \to D]$ for least-fixed-point arguments.

Definition (`fix`). Scott's fixed-point operator on endo-maps $[D \to D]$ (least fixpoint via **`toOrderHom`**).

Lemma (`fix_le`). **`fix f ≤ x`** from any prefix point **`f x ≤ x`**.

Lemma (`fix_eq`). **`f (fix f) = fix f`**.

Lemma (`fix_mono`). **`fix`** is monotone in the Scott map argument.

Lemma (`fix_unique`). Any least prefix point agrees with **`fix f`**.

Lemma (`fix_preservesDirectedSup`). **`fix : [D \to D] \to D`** preserves directed suprema.

Definition (`fixMap`). The Scott-continuous **`[D \to D] \to D`** map packaging **`fix`**; **`fixMap_apply`**.

Definition (`le`), `lt`. Pointwise order: $f \le g$ when $f(x) \le g(x)$ for all x.

Lemma (`le_refl'`). Reflexivity of the pointwise order.

Lemma (`le_trans'`). Transitivity.

Lemma (`le_antisymm'`). Antisymmetry.

Lemma (`lt_iff_le_not_ge'`). Strict order as "$\le$ and not $\ge$"; feeds **`instPartialOrder`**.

Instance (`instPartialOrder`). Pointwise order on **`ScottMap D D'`**.

Lemma (`le_def`). **`f ≤ g`** iff pointwise inequality on the coercion.

Lemma (`preservesDirectedSup_coe`). For nonempty directed $S \subseteq D$, $f(\bigsqcup S) = \bigsqcup f[S]$ (Proposition 2.5 on the coercion).

Lemma (`monotone`). The underlying function is monotone.

Lemma (`pointwise_sSup_preservesDirectedSup`). For $\mathcal{F} \subseteq [D \to D']$, the map $x \mapsto \bigsqcup\{f(x) \mid f \in \mathcal{F}\}$ preserves directed suprema.

Lemma (`sSupMaps_continuous`). That pointwise sup is Scott-continuous.

Definition (`sSupMaps`). The Scott map whose value at x is that pointwise sup; **`sSupMaps_apply`** is definitional.

Instance (`instSupSet`). **`sSup F`** is **`sSupMaps F`**.

Lemma (`sSup_apply`). `(sSup F) x = \bigsqcup \{ f(x) \mid f \in F \}`.

Theorem (`isLUB_sSup`). `sSup F` is a least upper bound of F in the pointwise order.

Definition (`instCompleteLattice`). `ScottMap D D'` is a complete lattice via `completeLatticeOfSup` (sup-only here; meets are inherited from the complete lattice structure on D' at each point).

Lemma (`preservesDirectedSup_comp`). If $f : D' \to D''$ and $g : D \to D'$ preserve directed suprema, so does $f \circ g$.

Definition (`comp`). Composition of Scott maps; `comp_apply` is `(f \circ g)(x) = f(g(x))`.

Lemma (`continuous`). The subtype proof: Scott continuity of the coercion.

Definition (`idMap`). The identity Scott endo-map; `idMap_apply` is reflexivity at x.

Lemma (`bot_apply`). `(⊥) x` $= \bot$ in D'.

Lemma (`sup_apply`). `(f \sqcup g)(x) = f(x) \sqcup g(x)`.

Lemma (`sInf_image_le_of_mem`). For Scott-open $U \ni y$, $\sqcap f'[U] \sqsubseteq f'(y)$ on the coercion $f' : D \to D'$.

Theorem (`eq_sSup_openInfs`). When D' is a continuous lattice, $f'(y)$ is the directed supremum over Scott-open $U \ni y$ of the values $\sqcap f'[U]$ (open-set `sInf` representation of a Scott map at a point).

Scott's *continuous* lattice structure on $[D \to D']$ (`ContinuousLattice (ScottMap D D')`) is proved later via `stepMap.isContinuousLattice`, not in this file.

2.4.4 Step function (pointwise) ✓

Pointwise values for Scott's $\overrightarrow{e}[e, e']$ before packaging as a **`ScottMap`**.

Scott's Theorem 3.3 proof uses the pointwise step values that later become the step maps in **`ScottMap D D'`**. For $e \in D$, $e' \in D'$, and $x \in D$, **`stepFun e e' x`** is that value before continuity is packaged (the case split $e'/\bot$ from $e \ll x$).

Namespace **`stepFun`** collects:

Lemma (`of_wayBelow`). If $e \ll x$, then **`stepFun e e' x = e'`**.

Lemma (`of_not_wayBelow`). If $\neg(e \ll x)$, then **`stepFun e e' x = \bot`**.

Theorem (`preservesDirectedSup`). **`stepFun e e'`** preserves directed suprema (hence is Scott-continuous).

`stepFun.lean`

2.4.5 Step map $\overrightarrow{e}[e, e']$ ✓

Scott's step functions as elements of **`ScottMap D D'`** (Theorem 3.3).

For $e \in D$ and $e' \in D'$, **`stepMap e e'`** is Scott's step function $\overrightarrow{e}[e, e'] \in$ **`ScottMap D D'`** (built from **`stepFun`** and **`stepFun.preservesDirectedSup`**).

Namespace **`stepMap`** collects the step-function tools used in Theorem 3.3(a):

Lemma (`apply_of_wayBelow`). If $e \ll x$, then `(stepMap e e') x = e'`.

Lemma (`le_of_wayBelow`). If $e' \ll f(e)$, then `stepMap e e' ≤ f` in **`ScottMap D D'`**.

Lemma (`wayBelow`). If $e' \ll f(e)$, then `stepMap e e' ≪ f`.

Theorem (`pointwise_sSup`). For **`ContinuousLattice D`**, **`ContinuousLattice D'`**, $f \in$ **`ScottMap D D'`**, and $x \in D$, $(fx) = \bigsqcup\{\, e' \mid \exists e,\ e \ll x \wedge e' \ll f(e) \,\}$.

Theorem (`isContinuousLattice`). If **`ContinuousLattice D`** and **`ContinuousLattice D'`**, then **`ScottMap D D'`** is a continuous lattice (Theorem 3.3(a); proof combines **`pointwise_sSup`**, **`wayBelow`**, and **`apply_of_wayBelow`**).

2.4.7 Product topology on $[D \to D']$ ✓

For complete lattices D and D', the library topologizes **`ScottMap D D'`** (Scott-continuous maps $D \to D'$; see Elements of $[D \to D']$) with the *product* or pointwise-convergence topology: subbasic sets have the same shape as in Definition 3.1,

$$\{f : f(x) \in U\}$$

with $x \in D$ and $U \subseteq D'$ open in **`scottTopologicalSpace`**.

Definition (`scottMapInducedPiTopology D D'`). `TopologicalSpace (ScottMap D D')` induced from the pi topology on D'^D (each fiber carries **`scottTopologicalSpace`**) along the inclusion **`ScottMap D D' ↪ (D → D')`**.

Namespace **`scottMapInducedPiTopology`** packages the equivalent eval subbase (parallel to **`scottFunctionTopology`** in Definition 3.1):

Definition (`pointwiseSubbasis`). Subbasic sets $\{\, f \mid f(x) \in U \,\}$ for $f \in$ **`ScottMap D D'`**, $x \in D$, and $U \subseteq D'$ Scott-open.

Definition (`pointwiseTopology`). `generateFrom (pointwiseSubbasis D D').`

Lemma (`subbasic_isOpen`). For Scott-open $U \subseteq D'$ and $x \in D$, the subbasic set $\{\, f \mid f(x) \in U \,\}$ is open in **`pointwiseTopology D D'`**.

Theorem (`eq_induced_pi`). `pointwiseTopology D D' = scottMapInducedPiTopology D D'` — the eval subbase and the induced pi topology agree.

When D and D' are continuous lattices, the Scott topology on **`ScottMap D D'`** (from **`isContinuousLattice`** in namespace **`stepMap`**) agrees with this product topology:

Lemma (`pointwiseSubbasic_scottOpen`). Eval subbasic sets are Scott-open in **`ScottMap D D'`**.

Lemma (`wayBelow_le_finset_sup_step`). From $\varphi \ll$ **`g`**, a finite finset of step maps majorizes φ.

Lemma (`wayBelow_finset_sup`). A finite sup of way-below elements is way-below **`g`**.

Theorem (`scottTopology_eq_pointwise`). On **`ScottMap D D'`**, **`scottTopologicalSpace = pointwiseTopology D D'`** (uses the three lemmas above).

Theorem (`scottTopology_eq_inducedPi`). On **`ScottMap D D'`**, **`scottTopologicalSpace = scottMapInducedPiTopology D D'`** (from **`scottTopology_eq_pointwise`** and **`eq_induced_pi`**). This is Theorem 3.3(b).

2.4.8 Theorem 3.3 ✓

3.3 Theorem. If D and D' are continuous lattices, then so is $[D \to D']$ under the induced partial ordering with the lattice topology agreeing with the product topology.

Proof: The argument is "pointwise." Thus, the constant function with value $\bot \in D'$ is obviously continuous and is the $\bot$ of $[D \to D']$ by 3.2. Since by 2.7 the lattice operation $\sqcup$ on D' is continuous, then if $f, g \in [D \to D']$ the composition $f \sqcup g$, defined by

$$(f \sqcup g)(x) = f(x) \sqcup g(x)$$

for all $x \in D$, is also continuous and represents the lub of f, g in $[D \to D']$. (The same arguments apply to $\top$ and $\sqcap$, so $[D \to D']$ is at least a lattice.) To show that $[D \to D']$ is complete it is sufficient now to show that lubs of directed subsets exist. So let $\mathcal{F} \subseteq [D \to D']$ be directed. Define a function from D into D' by the equation:

$$(\bigsqcup \mathcal{F})(x) = \bigsqcup\{f(x) : f \in \mathcal{F}\},$$

for all $x \in D$. If we can show that $\bigsqcup \mathcal{F}$ is continuous, then being in $[D \to D']$ it has to be the lub. Consider $U \subseteq D'$, an open subset. Taking the inverse image and remembering that $\mathcal{F}$ is directed, we find:

$$\{x : (\bigsqcup \mathcal{F})(x) \in U = \bigcup x : f(x) \in U : f \in \mathcal{F}\}.$$

This is an open set, and so $\bigsqcup \mathcal{F}$ is indeed continuous. (Warning: the infinite $\sqcap \mathcal{F}$ are not in general computed pointwise; however, it is easy to extend the above argument to show that arbitrary $\bigsqcup \mathcal{F}$ are.)

To show that $[D \to D']$ is continuous, we establish first that for $f \in [D \to D']$

$$f = \bigsqcup \overrightarrow{e}[e, \{e'] : e' \ll f(e)\},$$

where e ranges over D and e' over D', and where the function $\overrightarrow{e}[e, e']$ is defined by:

$$\overrightarrow{e}[e, e'](x) = \begin{cases} e' & \text{if } e \ll x, \\ \bot & \text{if not,} \end{cases}$$

for all $x \in D$. Call the function on the right f'. Calculate:

$$f'(x) = \bigsqcup \overrightarrow{e}[e, e'](x) : e' \ll f(e)$$

$$= \bigsqcup\{e' : \exists e \ll x\ [e' \ll f(e)]\}$$

$$= \bigsqcup\{e' : e' \ll f(x) = f(x)\}.$$

With the equation for f proved, note next that for all $g \in [D \to D']$, $e' \ll g(e)$ implies $\overrightarrow{e}[e, e'] \sqsubseteq g$ by an easy pointwise argument. If we let $V = \{g : e' \ll g(e)\}$, we see then that V is open in the product topology and that $\overrightarrow{e}[e, e'] \sqsubseteq \sqcap V$. We may then conclude that $f = \bigsqcup\{\sqcap V : f \in V\}$, which proves both that $[D \to D']$ is a continuous lattice and that the two topologies agree by the remark following 2.4. □

Pointwise $\sqcup$, $\top$, and $\bot$ yield a complete lattice on **`ScottMap D D'`** when D and D' are complete (**`ScottMap.instCompleteLattice`**); directed suprema are computed pointwise (**`isLUB_sSup`**, **`sSupMaps`**). Scott's step functions are **`stepMap e e'`**; **`stepMap.pointwise_sSup`**,

stepMap.wayBelow, and **stepMap.apply_of_wayBelow** formalize $f = \bigsqcup \overrightarrow{e}[e, e']$ (see **stepMap.isContinuousLattice** in Step map $\overrightarrow{e}[e, e']$). The product topology and its agreement with the Scott topology are in Product topology on $[D \to D']$ (**scottMapInducedPiTopology.scottTopology_eq_pointwise**, **scottTopology_eq_inducedPi**).

Theorem (theorem_3_3). If **ContinuousLattice D** and **ContinuousLattice D'**, then **ScottMap D D'** is a continuous lattice and its Scott topology equals **scottMapInducedPiTopology.pointwiseT D D'**.

Proof. theorem_3_3.lean combines **stepMap.isContinuousLattice** and **scottMapInducedPiTopol eq_pointwise**. □

The above theorem might possibly be generalized to $[X \to D]$ where X is merely a T_0-space, but I was unable to see the argument. In any case we are mostly interested in the continuous lattices. Note as a consequence of our proof:

2.4.9 Corollary 3.4 ✓

3.4 Corollary. For continuous lattices D and D', the evaluation map:

$$\mathrm{eval} : [D \to D'] \times D \to D'$$

is continuous.

Proof: Here $\mathrm{eval}(f, x) = f(x)$. With f fixed, this is obviously continuous. With x fixed, we proved the continuity above with our calculation of $\bigsqcup \mathcal{F}$ in view of 2.5. Hence applying 5.3 and 2.6, we conclude that eval is jointly continuous. □

This result gives only one example of the masses of continuous functions that are available on continuous lattices. As another fundamental example we have:

Namespace **corollary_3_4** collects the evaluation tools; Scott's corollary is assembled from them:

Lemma (`eval_on_C`). For $x \in D$, application at x is continuous as a map **`ScottC D D' → D'`** when the function space carries **`scottFunctionTopology`** with Scott topologies on D and D'.

Theorem (`preservesDirectedSup`). Joint evaluation **`(f, x) ↦ f(x)`** on **`ScottMap D D' × D`** preserves directed suprema (via Propositions 2.5 and 2.6).

Theorem (`jointly_continuous`). The evaluation map **`ScottMap D D' × D → D'`** is Scott-continuous.

Theorem (`corollary_3_4`). Specialization of **`eval_on_C`** to **`ScottC D D'`** (the x-fixed step in Scott's proof).

For continuous lattices D, D', and D'', Scott's functional abstraction

$$\mathrm{lambda}(f)(x)(y) = f(x, y)$$

maps $f \in [[D \times D'] \to D'']$ to an element of $[D \to [D' \to D'']]$ (using Theorem 3.3 on nested function spaces). The library names that map **`scottLambda`**.

Definition (`scottLambda.at`). For $f \in$ **`ScottMap (D × D') D''`** and $x \in D$, **`scottLambda.at f x`** is the Scott map $y \mapsto f(x, y)$ in **`ScottMap D' D''`**.

Definition (`scottLambda`). **`scottLambda f`** is the Scott map $x \mapsto$ **`scottLambda.at f x`** in **`ScottMap D (ScottMap D' D'')`**.

On complete lattices, currying uses two pointwise **`sSup`** facts (same file, no separate module):

Lemma (`sSup_image_prod_mk_left`). $\bigsqcup\{\,(x, y) \mid y \in S\,\} = (x, \bigsqcup S)$ for nonempty $S \subseteq D'$.

Lemma (`sSup_image_prod_mk_right`). $\bigsqcup\{\,(x, y) \mid x \in S\,\} = (\bigsqcup S, y)$ for nonempty $S \subseteq D$.

Namespace **`scottLambda`** collects the currying and section tools used to build those maps:

Lemma (`curry_right`). For fixed $x \in D$, the section $y \mapsto f(x, y)$ preserves directed suprema.

Lemma (`curry_left`). For fixed $y \in D'$, the section $x \mapsto f(x, y)$ preserves directed suprema.

Theorem (`outer`). For $f \in$ **`ScottMap (D × D') D''`**, the map $x \mapsto$ **`scottLambda.at f x`** preserves directed suprema.

Lemma (`apply`). **`((scottLambda f x) : ScottMap D' D'') y = f(x,y)`** (definitional).

The map **`scottLambda`** itself (on carriers **`ScottMap (D × D') D''`** and **`ScottMap D (ScottMap D' D'')`**) preserves directed suprema in the function variable; lubs on Scott maps are computed pointwise (Theorem 3.3).

Theorem (`preservesDirectedSup`). **`PreservesDirectedSup scottLambda`** (namespace **`scottLambda`**, `scottLambda.lean`).

This is the directed-supremum input to Scott continuity of functional abstraction (Proposition 3.5).

2.4.11 Proposition 3.5 ✓

3.5 Proposition. For continuous lattices D, D', and D'', the map of functional abstraction:

$$\text{lambda} : [[D \times D'] \to D''] \to [D \to [D' \to D'']]$$

is continuous.

Proof: Here lambda is defined by:

$$\text{lambda}(f)(x)(y) = f(x, y)$$

where $f \in [[D \times D'] \to D'']$ and $x \in D$ and $y \in D'$. What is particularly interesting here is that by virtue of 3.3 we are making use of $[D \to [D' \to D'']]$ as a continuous lattice. The principle being stated here can be formulated more broadly in this way:

> If an expression $\mathcal{E}(x, y, z, \dots)$ is continuous in all its variables $x, y, z, \dots$ with values in D' as x ranges in D, then the expression
>
> $$\lambda x : D.\mathcal{E}(x, y, z, \dots)$$
>
> with values in $[D \to D']$ is continuous in the remaining variables $y, z, \dots$.

The λ-notation is a notation for functions, where in the above the variable after the λ is the *argument* and the expression after the . is the *value* (as a function of the argument). Thus we could write:

$$\text{lambda} = \lambda f : [[D \times D'] \to D''].\lambda x : D.\lambda y : D'.f(x, y),$$

and, because $f(x, y)$ is continuous in f, x, and y, our conclusion follows. But often it is more readable not to write equations between functions but rather equations between values for definitional purposes.

The proof of the principle is easy. For let the variable y, say range over D'' and let $S \subseteq D''$ be a directed subset. Then

$$\lambda x : D.\mathcal{E}(x, \bigsqcup S, z, \dots) = \lambda x : D.\bigsqcup \mathcal{E}(x, y, z, \dots) : y \in S \quad = \bigsqcup \lambda x : D.\mathcal{E}(x, y, z, \dots) : y \in S,$$

because the lubs of functions are computed pointwise. □

We need not enumerate the many corollaries that follow easily now from this result. We mention, however, that composition $f \circ g$ of functions (on continuous lattices) is continuous in the two function variables, where we write

$$(f \circ g)(x) = f(g(x)).$$

2.4.12 Retractions and extensions ✓

What will be useful will be to return at this point to a discussion of the injective properties of continuous lattices. If one continuous lattice is a subspace of another it is of course a retract. This relationship between spaces can be given by a pair of continuous maps

$$i : D \to D' \quad \text{and} \quad j : D' \to D,$$

where

$$j \circ i = \mathrm{id}_D = \lambda x : D.x.$$

The composition $i \circ j : D' \to i(D)$ is the retraction onto the subspace corresponding to D under i. Now if we have a diagram:

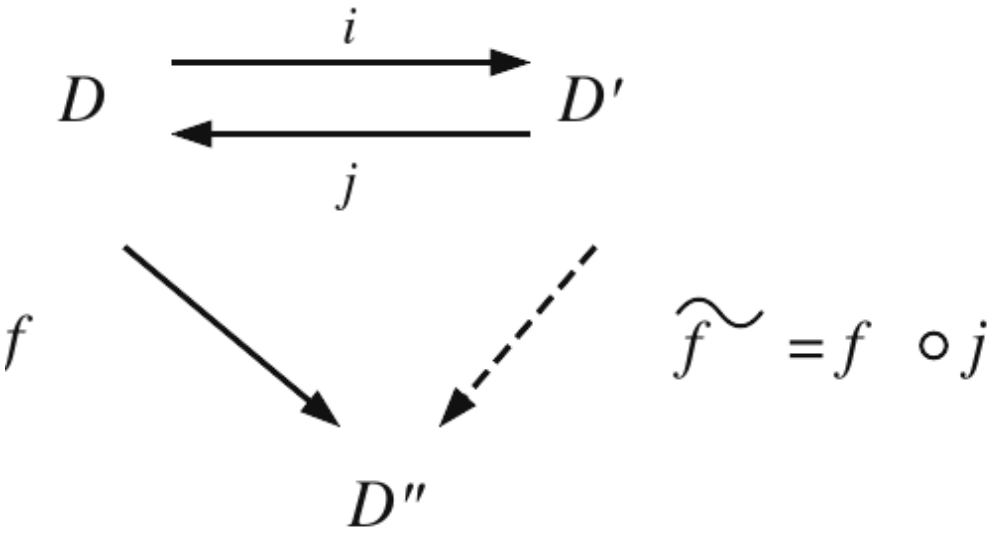

Figure 12: D arrow i to D prime, arrow j back; solid f from D to D double prime; dashed arrow from D prime to D double prime labeled f tilde equals f compose j

the given continuous f is at once extendable from D to D' by the obvious definition of $\tilde{f}$. This $\tilde{f}$ is not the $\bar{f}$ used in the proof of 2.11, and it will be well to sort out the connections. On one side note that if f' is any function which extends f, then we have $f = f' \circ i$. But this implies

$$\tilde{f} = f \circ j = f' \circ i \circ j,$$

which shows that $\tilde{f}$ is a "degraded" version of f'. There is one situation where this type of degrading is especially nice.

structure retraction (D₀ D₀' D₁ D₁' : Type*)
    [CompleteLattice D₀] [CompleteLattice D₀'] [CompleteLattice D₁] [CompleteLattice D₁
    '] where
  incl : ScottMap D₀ D₁ → ScottMap D₀' D₁'
  retr : ScottMap D₀' D₁' → ScottMap D₀ D₁
  retr_incl : ∀ f, retr (incl f) = f

end ScottMap

end DomainTheory.ContinuousLattice
```

2.4.13 Definition 3.6 ✓

3.6 Definition. A continuous lattice D is said to be a *projection* of a continuous lattice D' iff there are a pair of continuous maps

$$i : D \to D' \quad \text{and} \quad j : D' \to D$$

such that not only

$$j \circ i = \mathrm{id}_D,$$

but also

$$i \circ j \sqsubseteq \mathrm{id}_{D'}.$$

Thus, in case our retraction is a projection, we have $\tilde{f} \sqsubseteq f'$, which means that $\tilde{f}$ is the *minimal* extension of $f \in [D \to D'']$ to a function in $[D' \to D'']$. We will discuss the nature of $\tilde{f}$ in a moment. But before we do we pause to remark that the correspondence $f \rightsquigarrow \tilde{f}$ is *continuous*, and this fact is easily extended.

2.4.14 Function-space retraction and projection ✓

When D_n is a retraction (projection) of D'_n via $i_n : D_n \to D'_n$ and $j_n : D'_n \to D_n$, Proposition 3.7 lifts that data to the function spaces $[D_0 \to D_1]$ and $[D'_0 \to D'_1]$. Scott writes the lifted pair as $\vec{i}$ and $\vec{j}$:

$$\vec{i}(f) = i_1 \circ f \circ j_0, \qquad \vec{j}(f') = j_1 \circ f' \circ i_0$$

for $f \in [D_0 \to D_1]$ and $f' \in [D'_0 \to D'_1]$. The formalization packages lattice retractions **`ContinuousLatticeRetraction`** (and projections **`ContinuousLatticeProjection`**) from Continuous lattice retraction and Continuous lattice projection; map-space carriers **`ScottMap.retraction`** and **`ScottMap.projection`** from Retractions and extensions and Definition 3.6.

Definition (`FunctionSpace.retraction`). From **`R0 : ContinuousLatticeRetraction D0 D0'`** and **`R1 : ContinuousLatticeRetraction D1 D1'`**, build **`ScottMap.retraction D0 D0' D1 D1'`** with **`incl f = R1.incl ∘ f ∘ R0.retr`** and **`retr f' = R1.retr ∘ f' ∘ R0.incl`**.

Definition (`FunctionSpace.projection`). From **`P0`** and **`P1`** as continuous lattice projections, the same **`incl`** / **`retr`** formulas on **`ScottMap`**, plus **`incl_retr_le`** from the lattice projection inequalities.

2.4.16 Scott subspace extension ✓

When Y carries the Scott topology and $e : X \to Y$ is a subspace embedding, Scott's **subspace extension** $\bar{f} : Y \to D$ of $f : X \to D$ is built from open neighborhoods of $y \in Y$ and the infima $\sqcap f(e^{-1}(U))$ over $U \ni y$. The formalization lives in `scottSubspaceExtend.lean`.

Definition (`scottSubspaceExtend.inf`). For Scott-open $U \subseteq Y$, `inf e f U` is $\sqcap\{f(x) \mid e(x) \in U\}$.

Definition (`scottSubspaceExtend`). `scottSubspaceExtend e f y` is $\bigsqcup\{d \mid \exists U$ Scott-open, $y \in U,\ d = \inf e\, f\, U\}$.

Namespace **`scottSubspaceExtend`**:

Lemma (`inf_mono`). Monotonicity in the domain map $f \le g$ on X.

Lemma (`inf_eq_of_ext`). Agreement on $e(X)$ implies equal **`inf`**.

Lemma (`inf_eq_of_comp`). Relates **`inf e f U`** to $\sqcap f'(e(X) \cap U)$ when $f' : [Y \to D]$ extends f on $e(X)$.

Lemma (`sInf_image_le_of_subset`). Larger index set lowers **`sInf`** on images.

Lemma (`inf_mono_incl_apply`). For a continuous-lattice projection **`P : D ⇄ D'`**, **`P.incl (inf e f U) ≤ inf e (λ x, P.incl (f x)) U`**.

Lemma (`inf_mono_retr`). For the same **`P`**, **`P.retr (inf e g U) ≤ inf e (λ x, P.retr (g x)) U`**.

Lemma (`inf_mono_incl`). If **`∀ x, f x = P.retr (g x)`** on X, then **`inf e (λ x, P.incl (f x)) U ≤ inf e g U`**.

Lemma (`incl_inf`). Under the same agreement **`f = P.retr ∘ g`** on X, **`P.incl (inf e f U) ≤ inf e g U`** (**`inf_mono_incl_apply`** then **`inf_mono_incl`**).

Lemma (`mono`). / `eq_of_ext`. — for the full extension **`scottSubspaceExtend`**.

Theorem (`maximal`). Any Scott map $f' : Y \to D$ extending f on $e(X)$ satisfies $f'y \le \bar{f}(y)$ (uses **`ScottMap.eq_sSup_openInfs`** from Elements of $[D \to D']$).

2.4.17 Proposition 3.8 ✓

Returning now to $\bar{f}$ we can prove:

3.8 Proposition. If D is a continuous lattice and $e : X \to Y$ a subspace embedding, then for each $f : X \to D$, the function $\bar{f} : Y \to D$ given by the formula

$$\bar{f}(y) = \bigsqcup \{ \sqcap f(x) : e(x) \in U : y \in U \},$$

where U ranges over open subsets of Y and x over X, is the maximal extension of f to a function in the partially ordered set $[Y \to D]$.

Proof: We are saying that $\bar{f}$ is the maximal solution to the equation

$$f = \bar{f} \circ e.$$

We already know it is a solution, so let f' be any other. We have

$$f'(y) = \bigsqcup \sqcap f'(z) : z \in U : y \in U \quad \sqsubseteq \bigsqcup \sqcap f'(z) : z \in e(X) \cap U : y \in U = \bigsqcup \sqcap f'(e(x)) : e(x) \in U : y \in U \quad = \bigsqcup \{\sqcap$$

which establishes that $f' \sqsubseteq \bar{f}$. $\square$

By the same argument we could show that $\bar{f}$ is the maximal solution of $\bar{f} \circ e \sqsubseteq f$. An interesting question is whether the correspondence $f \rightsquigarrow \bar{f}$ is continuous. I very much doubt it, but at this moment a counterexample escapes me. It is clear that the correspondence is monotonic, for if $f \sqsubseteq g$, then the formula of 3.8 shows that $\bar{f} \sqsubseteq \bar{g}$. This gives us a neat argument for the previous remark: if $g \circ e \sqsubseteq f$, then

$$\overline{g \circ e} \sqsubseteq \bar{f}.$$

But $g \circ e = \overline{g \circ e} \circ e$, so by 3.8, $g \sqsubseteq \overline{g \circ e}$, and $\bar{f}$ is thus maximal.

In the case that the range spaces are being extended, the following lemma relating the extensions will be very useful when we consider inverse limits.

2.4.18 Lemma 3.9 ✓

3.9 Lemma. Consider the diagram:

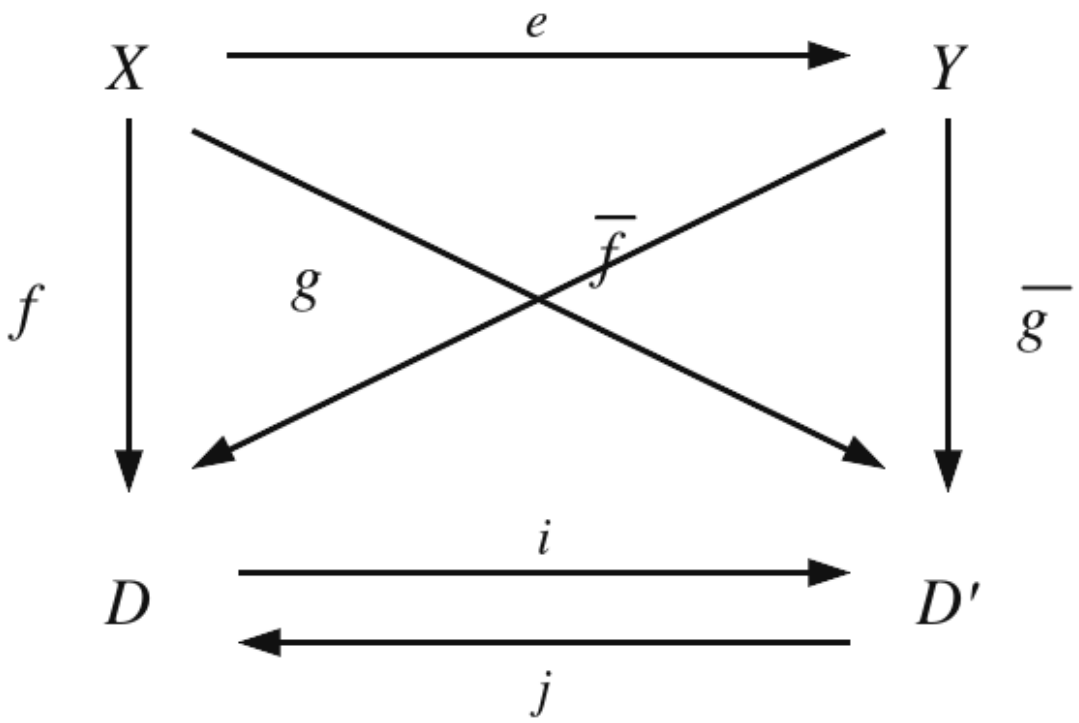

Figure 13: Lemma 3.9 diagram. Top: X to Y by e. Left: f down to D. Right: g bar down to D prime. Diagonals cross: g from X to D prime, f bar from Y to D. Bottom: i from D to D prime and j back.

where the upper row is a subspace embedding and the lower is a projection. If the given functions f and g are extended to $\bar{f}$ and $\bar{g}$ as in 3.8, and if $f = j \circ g$, then $\bar{f} = j \circ \bar{g}$ also.

Proof: $\bar{f}$ and $\bar{g}$ are maximal solutions of $f = \bar{f} \circ e$ and $g = \bar{g} \circ e$. Therefore since

$$f = j \circ g = j \circ \bar{g} \circ e,$$

we see that

$$j \circ \bar{g} \sqsubseteq \bar{f}.$$

Note also that

$$i \circ \bar{f} \circ e = i \circ f = i \circ j \circ g \sqsubseteq g,$$

and so by the remark following 3.8, we have

$$i \circ \bar{f} \sqsubseteq \bar{g}.$$

Therefore

$$\bar{f} = j \circ i \circ \bar{f} \sqsubseteq j \circ \bar{g},$$

which proves the equality. □

Whether this lemma is true for retractions in any form, I do not know. My proof seems to require the stronger projection relationship. I suspect there may be difficulties. In general projections are better behaved than retractions. By the way the word projection seems to be properly used in 3.6, for the projection $j : D \times D' \to D$ of the Cartesian product of two continuous lattices onto the first factor *is* a projection with partial inverse $i : D \to D \times D'$ defined by

$$i(x) = (x, \bot)$$

for $x \in D$.

2.4.19 Proposition 3.10 ✓

3.10 Proposition. If the continuous lattice D is a projection of the continuous lattice D' via the pair of maps i, j; then for all $S \subseteq D$ and all $x, y \in D$ we have:

(i) $i(\bigsqcup S) = \bigsqcup\{i(x) : x \in S\}$,

(ii) $i(x) = i(y)$ implies $x = y$,

(iii) $x \ll y$ implies $i(x) \ll i(y)$.

Conversely, if a map $i : D \to D'$ satisfies (i)–(iii), then there exists a continuous $j : D' \to D$ making D a projection of D', and in fact j is uniquely determined by:

(iv) $j(x') = \bigsqcup\{x \in D : i(x) \sqsubseteq x'\}$

for all $x' \in D'$.

Proof: Equation (i) holds for directed $S \subseteq D$ because i is continuous. To have it hold for arbitrary S it is only necessary to check it for finite sets, because every lub is the directed lub of finite sublubs. (The last word of that sentence is an unfortunate accident.) Further, to check the equation for finite sets it is enough

to check it for the empty set and for two element sets. Thus, $i(\bot) = \bot$, because $j(i(\bot)) = \bot$ and since $\bot \sqsubseteq i(\bot)$,

$$j(\bot) \sqsubseteq j(i(\bot)) = \bot,$$

so $j(\bot) = \bot$. Whence $i(\bot) = i(j(\bot)) \sqsubseteq \bot$. Next $i(x \sqcup y) = i(x) \sqcup i(y)$, because first

$$i(x) \sqcup i(y) \sqsubseteq i(x \sqcup y)$$

by monotonicity. Then note that

$$i(x) \sqsubseteq i(x) \sqcup i(y)$$

and so

$$x = j(i(x)) \sqsubseteq j(i(x) \sqcup i(y)).$$

Similarly

$$y \sqsubseteq j(i(x) \sqcup i(y)),$$

whence

$$x \sqcup y \sqsubseteq j(i(x) \sqcup i(y)).$$

But then

$$i(x \sqcup y) \sqsubseteq i(j(i(x) \sqcup i(y))) \sqsubseteq i(x) \sqcup i(y),$$

which completes the argument for equation (i).

Condition (ii) is obvious. For (iii) we argue as follows. Assume $x \ll y$. Since D' is continuous we can write:

$$i(y) = \bigsqcup \{z' \in D' : z' \ll i(y)\},$$

and conclude by the continuity of j that:

$$y = j(i(y)) = \bigsqcup j(z') : z' \ll i(y).$$

But $x \ll y$, so $x \ll j(z')$ for some $z' \ll i(y)$. Now $x \sqsubseteq j(z')$ follows; therefore $i(x) \sqsubseteq i(j(z')) \sqsubseteq z'$. Thus $i(x) \ll i(y)$.

Turning now to the converse, assume of the map i that it satisfies (i)–(iii). Compute:

$$i(j(x')) = \bigsqcup i(x) : i(x) \sqsubseteq x' \sqsubseteq x'.$$

This is correct because i is continuous and the set $\{x : i(x) \sqsubseteq x'\}$ is directed in view of condition (i). Thus $i \circ j \sqsubseteq \mathrm{id}_{D'}$. Note that by virtue of (i) and (ii) it is the case that

$$i(x) \sqsubseteq i(y) \text{ implies } x \sqsubseteq y.$$

(The reason is that $x \sqsubseteq y$ is equivalent to $x \sqcup y = y$.) This remark allows us to compute:

$$j(i(y)) = \bigsqcup\{x : i(x) \sqsubseteq i(y)\}$$
$$= \bigsqcup\{x : x \sqsubseteq y = y\}.$$

Hence, $j \circ i = \mathrm{id}_D$. It remains to show that j is continuous. Suppose $S' \subseteq D'$ is directed. Since j is by definition monotonic, it is sufficient to prove that

$$j(\bigsqcup S') \sqsubseteq \bigsqcup j(x') : x' \in S'.$$

Now

$$j(\bigsqcup S') = \bigsqcup\{x : i(x) \sqsubseteq \bigsqcup S'\},$$

so suppose $i(x) \sqsubseteq \bigsqcup S'$. Let $z \ll x$; whence $i(z) \ll i(x)$. Thus $i(z) \ll x'$ for some $x' \in S'$, and therefore $i(z) \sqsubseteq x'$. We obtain then $z \sqsubseteq j(x')$, which means that

$$z \sqsubseteq \bigsqcup j(x') : x' \in S'$$

holds for all $z \ll x$. By the continuity of D we conclude

$$x \sqsubseteq \bigsqcup j(x') : x' \in S'$$

holds for all x with $i(x) \sqsubseteq \bigsqcup S'$. The desired result follows. □

As a corollary of 3.10 we can easily see which *subspaces* of a continuous lattice D' are projections of it. Such a subspace $D \subseteq D'$ must first be closed under $\bigsqcup$. That is, if $S \subseteq D$, then $\bigsqcup S \in D$ for

all S, where the lub is taken in the sense of D'. The identity map on D will then satisfy (i) and (ii). But this is not enough, since we would not know that D is a continuous lattice, nor whether (iii) holds. The following additional condition would be sufficient, if assumed for all $y \in D$:

$$y = \bigsqcup\{x \in D : x \ll y\},$$

where $\ll$ is taken in the sense of D'. This implies that

$$y = \bigsqcup\{\sqcap(D \cap U) : y \in U\}$$

where U ranges over the open subsets of D' and where the $\sqcap$ is taken in the sense of D. This condition makes the subspace topology the same as the lattice topology on D and besides makes D continuous, which is just what we need. (Another way to put it is that whenever $z \ll y$, where $y \in D$ but $z \in D'$, then $z \sqsubseteq x \ll y$, for some $x \in D$.)

It seems a bit troublesome to characterize in a simple way just which maps $j : D' \to D$ are projections. (Other than saying outright that the map $i : D \to D'$ such that for all $x \in D$:

$$i(x) = \sqcap\{x' \in D' : x \sqsubseteq j(x')\}$$

is the continuous partial inverse to j.) But we can say very easily which continuous maps $j : D' \to D'$ are projections onto *subspaces*; namely, we must have

$$j = j \circ j \sqsubseteq \mathrm{id}.$$

The subspace in question then is:

$$D = \{x \in D' : j(x) = x\}.$$

This non-empty subspace is the exact range of j and is closed under $\bigsqcup$. Let $y \in D$. Then if $x' \ll y$ in D', we find $j(x') \sqsubseteq x' \ll y$. Thus since

$$y = \bigsqcup\{x' \in D' : x' \ll y\},$$

we see that

$$y = j(y) = \bigsqcup\{j(x') : x' \ll y\}.$$

But each $j(x') \in D$, so $y = \bigsqcup\{x \in D : x \ll y\}$, as desired.

The foregoing discussion suggests looking more closely at the space of all projections of a continuous lattice since they are so easily characterized.

2.4.21 Proposition 3.12 ✓

3.12 Proposition. For a continuous lattice D the space J_D of projections forms a complete lattice as a $\bigsqcup$-closed subspace of $[D \to D]$.

Proof: The constant function $\bot \in J_D$ obviously, so J_D contains $\bigsqcup \emptyset$. Suppose $j, k \in J_D$. We wish to show that $j \sqcup k \in J_D$. Compute:

$$(j \sqcup k)((j \sqcup k)(x)) = j(j(x) \sqcup k(x)) \sqcup k(j(x) \sqcup k(x)).$$

But note:

$$j(x) \sqsubseteq j(j(x)) \sqsubseteq j(j(x) \sqcup k(x)) \sqsubseteq j(x),$$

because $j(x) \sqcup k(x) \sqsubseteq x$. Similarly for $k(x)$. Therefore, we find that $(j \sqcup k) \circ (j \sqcup k) = j \sqcup k \sqsubseteq \mathrm{id}$.

Suppose finally that $S \subseteq J_D$ is directed. We wish to show that $\bigsqcup S \in J_D$. Clearly $\bigsqcup S \sqsubseteq \mathrm{id}$, so compute by continuity of $\circ$:

$$\bigsqcup S \circ \bigsqcup S = \bigsqcup \{j \circ j : j \in S\} = \bigsqcup \{j : j \in S\} = \bigsqcup S.$$

It follows that J_D is $\bigsqcup$-closed and hence is a complete lattice. $\square$

The significance of the above result becomes clearer if we consider the connection between projections and subspaces. Let us write:

$$D(j) = \{x \in D : j(x) = x\}.$$

For $j \in J_D$, each $D(j)$ is a projection of D onto a subspace. We show first that

$$j \sqsubseteq k \quad \text{iff} \quad D(j) \subseteq D(k).$$

Because if $j \sqsubseteq k$, then $j \sqsubseteq j \circ j \sqsubseteq k \circ j \sqsubseteq \mathrm{id} \circ j = j$. Therefore if $j(x) = x$, then $k(x) = k(j(x)) = j(x) = x$, which means that $D(j) \subseteq D(k)$. On the other hand, if $D(j) \subseteq D(k)$, then since $j(D) \subseteq D(j)$, we see that $k \circ j = j$, and so $j \sqsubseteq k \circ \mathrm{id} = k$. Hence J_D is isomorphic to the partially ordered set of subspaces of D that are projections. We thus conclude that these subspaces form a lattice. In fact, it is easy to show that

$$D(j \sqcup k) = x \sqcup \{y : x \in D(j)\}, y \in D(k).$$

Similarly, if S is a directed set of J_D, then $D(\bigsqcup S)$ is the $\bigsqcup$-closure in D of the subset:

$$\{\bigcup D(j) : j \in S.\}$$

These are not very deep facts, but their proofs were very much facilitated by the introduction of J_D and the utilization of the lattice structure of $[D \to D]$. Along the same line we can define for $j, k \in J_D$ a function $(j \to k) \in [D \to D] \to [D \to D]$ by the equation

$$(j \to k)(f) = k \circ f \circ j.$$

It is very easy to show that $(j \to k) \in J_{[D \to D]}$, that $(j \to k)$ is continuous in j and k, and that $[D \to D](j \to k)$ is isomorphic to $[D(j) \to D(k)]$. There are many other interesting operations on projections corresponding to other constructs besides these. And, just as with $(j \to k)$, the operations are

continuous. This makes it possible to prove existence theorems about subspaces by using results like the fixed-point theorem for continuous functions. It would be even nicer if J_D turns out to be a continuous lattice itself, but as far as I can tell this is not likely to be the case.

Before we turn to the iterated function-space construction by inverse limits, there are a couple of other connections between spaces and function spaces that are useful to know.

2.4.22 Proposition 3.13 ✓

3.13 Proposition. Every continuous lattice D is a projection of its function space $[D \to D]$.

Proof: Consider the following pair of mappings $\mathrm{con} : D \to [D \to D]$ and $\mathrm{min} : [D \to D] \to D$ where

$$\mathrm{con}(x)(y) = x$$

and

$$\mathrm{min}(f) = f(\bot)$$

for all $x, y \in D$ and $f \in [D \to D]$. They are obviously continuous. The map con matches every element of D with the corresponding *constant* function in $[D \to D]$. The map min associates to every function in $[D \to D]$ its *minimum* value in the partial ordering. The proof that this pair forms a projection is trivial. □

The pair con, min are not the only pair for making D a projection of $[D \to D]$. The following pair of maps were suggested by David Park:

$$\lambda x.\vec{e}[t, x] \quad \text{and} \quad \lambda f.f(t),$$

where x ranges over D, and f over $[D \to D]$, and where t is a fixed *isolated* element of D (that is, $t \ll t$ holds). The pair con and min will result if we set $t = \bot$. (Note that the expression $\vec{e}[t, x]$, though

continuous in x, is not continuous—or even monotonic—in the variable t.) A lattice may very well possess a large number of isolated

elements, whence a large number of projections. And furthermore this is the only way the function $j = \lambda f.f(t)$ can be a projection. For assume the existence of an inverse $i : D \to [D \to D]$ satisfying the proper conditions. Then it would be the case that

$$i(x)(t) = x$$

and

$$i(f(t))(y) \sqsubseteq f(y)$$

for all $x, y \in D$ and all $f \in [D \to D]$. We can prove for all $u \in D$, if $t \not\sqsubseteq u$, then

$$i(x)(u) = \bot$$

by substituting $\vec{e}[v, x]$ for f in the second equation above, where v is chosen so that $v \ll t$ but not $v \ll u$. But then note that

$$i(x)(t) = \bigsqcup\{i(x)(u) : u \ll t\}.$$

If not $t \ll t$, then $u \ll t$ implies $t \not\sqsubseteq u$, which leads to absurdity. Hence t must be isolated, and, as we noted earlier, the function i is uniquely determined as being the one we already knew. Aside from these pairs of projections one could obtain others by combinations with automorphisms. I was unable to determine whether there are further pairs of an essentially different nature.

The topic of projections in these spaces is rather interesting since one has in a way more freedom in T_0-spaces (particularly in injective spaces) than in ordinary spaces for defining functions. As another example, consider the Cartesian square $D \times D$. Aside from the two obvious projections onto D, there is also the "diagonal" system given by the pair:

$$\lambda x.(x, x) \qquad \text{and} \qquad \lambda(x, y).x \sqcap y$$

We shall note in the next section how the choice of an initial projection effects the construction of an inverse limit.

The projections are not the only useful functions in $[D \to D] \to D$. As a final example of what can be done in function spaces we mention the fixed-point operator.

2.4.23 Proposition 3.14 ✓

3.14 Proposition. *For a continuous lattice D there is a uniquely determined continuous mapping*

$$\mathrm{fix} : [D \to D] \to D$$

where for all $f \in [D \to D]$ and $x \in D$

$$f(\mathrm{fix}(f)) = \mathrm{fix}(f)$$

and whenever $f(x) \sqsubseteq x$, then $\mathrm{fix}(f) \sqsubseteq x$.
and whenever $f(x) \sqsubseteq x$, then

$$\mathrm{fix}(f) \sqsubseteq x.$$

Proof: The proof of the existence of minimal fixed points in complete lattices is well known, as was mentioned in the proof of 2.10.

To establish the continuity, it is sufficient to remark that since all functions $f \in [D \to D]$ are continuous, we have

$$\mathrm{fix}(f) = \bigsqcup_{n=0}^{\infty} f^n(\bot),$$

where $f^n(x) = f(f(\ldots f(x)\ldots))$ (n times). Thus fix is the point-wise lub of continuous functions on $[D \to D]$ and is thus itself continuous. □

2.5 Inverse limits ✓

Scott's §4 opens with a review of inverse limits for T_0-spaces: an inverse system and compatible sequences, the formal inverse limit type for $\langle D_n, P_n \rangle$, projections from the limit ($j_{\infty n}$), the mediating map into X_∞, and the turn to special inverse systems. The notes that follow build the projection tower ($\mathrm{projectionAlongTower}$, adjunction at one step), embeddings into the limit, lattice and topology on D_∞, and Propositions 4.1–4.4.

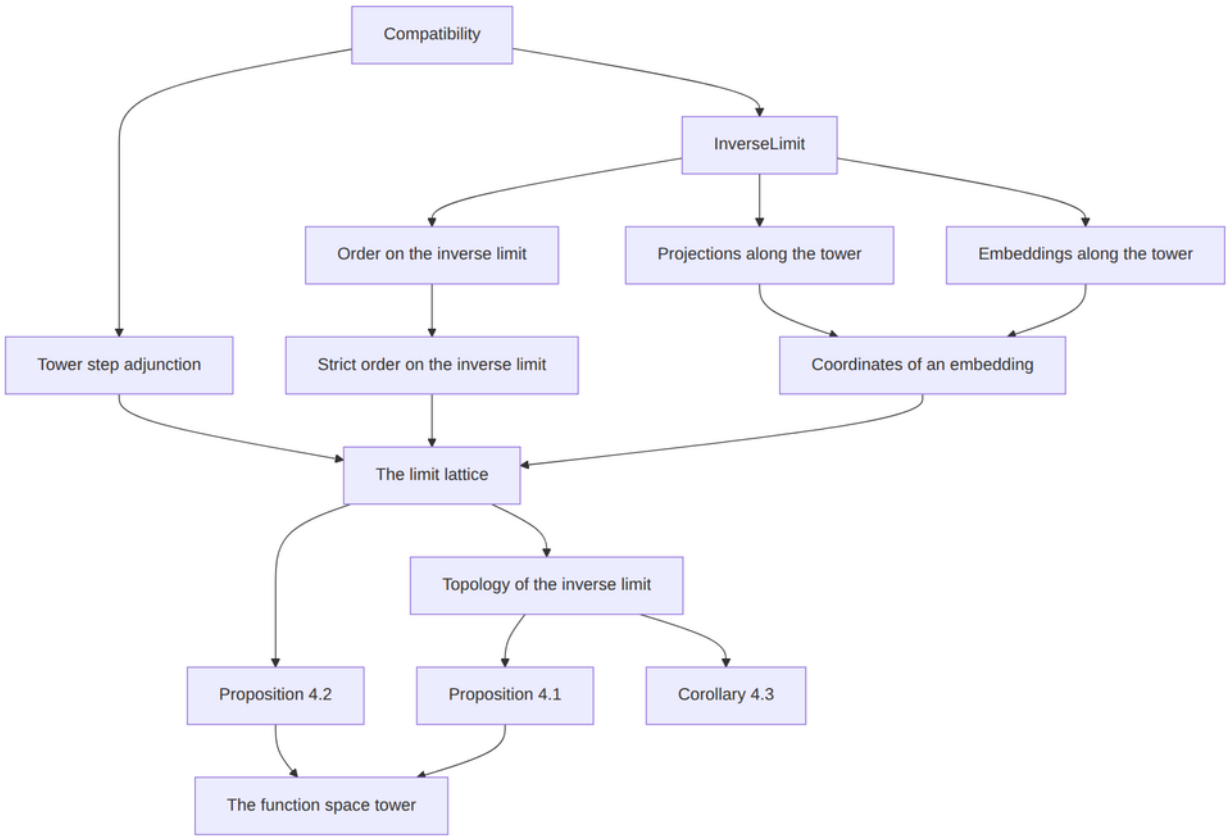

Figure 14: Inverse limits ✓.

2.5.1 Compatibility ✓

By an *inverse system of spaces* we understand as usual a sequence

$$\langle X_n, j_n \rangle_{n=0}^{\infty}$$

of T_0-spaces and continuous maps $j_n : X_{n+1} \to X_n$. The space X_∞, called the *inverse limit* of the sequence, is constructed in the familiar way as that subspace of the product space consisting of exactly those infinite sequences

$$x = \langle x_n \rangle_{n=0}^{\infty},$$

where for each n we have $x_n \in X_n$, and

$$j_n(x_{n+1}) = x_n.$$

For the continuous-lattice tower $\langle D_n, P_n \rangle$, j_n is **`(P n).retr`**.

Definition (`Compatible`). **`Compatible D P x`** holds when $\forall n,\ (P\,n).\mathrm{retr}\,(x\,(n+1)) = x\,n$ for **`x : ∀ n, D n`**.

`Compatible.lean`

```
module

public import DomainTheory.ContinuousLattice.FunctionSpaces.
    ContinuousLatticeProjection

@[expose] public section

namespace DomainTheory.ContinuousLattice

universe u

variable (D : ℕ → Type u) [∀ n, CompleteLattice (D n)]

variable (P : ∀ n, ContinuousLatticeProjection (D n) (D (n + 1)))

def Compatible (x : ∀ n, D n) : Prop := ∀ n, (P n).retr (x (n + 1)) = x n

end DomainTheory.ContinuousLattice
```

2.5.2 InverseLimit ✓

The preceding paragraphs describe X_∞ as the subspace of compatible sequences. For $\langle D_n, P_n \rangle$ the library name is **`InverseLimit D P`**.

Definition (`InverseLimit`). **`InverseLimit D P`** is the subtype of tuples **`x : ∀ n, D n`** that satisfy **`Compatible`** (Scott's D_∞ before topology and lattice structure are imposed).

`InverseLimit.lean`

```
module

public import DomainTheory.ContinuousLattice.InverseLimits.Compatible

@[expose] public section

namespace DomainTheory.ContinuousLattice

universe u
```

```
variable (D : ℕ → Type u) [∀ n, CompleteLattice (D n)]
variable (P : ∀ n, ContinuousLatticeProjection (D n) (D (n + 1)))

abbrev InverseLimit : Type u := {x : ∀ n, D n // Compatible D P x}

end DomainTheory.ContinuousLattice
```

2.5.3 Projections from the limit ✓

The space X_∞ is given the product topology, and the maps $j_{\infty\{n} : X_\infty \to X_n\}$ such that

$$j_{\infty n}(x) = x_n$$

are of course continous and satisfy the recursion equation:

$$j_{\infty n} = j_n \circ j_{\infty(n+1)}.$$

On **`InverseLimit D P`**, **`limitProjectionToLevel n`** is Scott's $j_{\infty n}$: the n-th coordinate **`y.1 n`**, packaged as a **`ScottMap`** once directed suprema on the limit are available.

2.5.4 The mediating map ✓

Besides this we have the expected extension property for any system of continuous maps

$$f_n : Y \to X_n$$

where for each n

$$f_n = j_n \circ f_{n+1}.$$

Because, we can define

$$\{f_\infty : Y \to X_\infty\}$$

by the equation

$$f_\infty(y) = \langle f_n(y) \rangle_{n=0}^{\infty}$$

for all $y \in Y$; whence

$$f_n = j_{\infty n} \circ f_\infty$$

holds.

Category theory (terms) **Diagram / tower.** For $\langle D_n, P_n\rangle$, write $j_n : D_{n+1} \to D_n$ for $(P\,n)$.retr and $i_n : D_n \to D_{n+1}$ for $(P\,n)$.incl. This is a diagram indexed by $\mathbb{N}$ (vertices D_n, bonds the j_n).

Inverse limit. A **limit** of that diagram is an object D_∞ together with **projections** $j_{\infty\{n} : D_\infty \to D_n\}$ such that $j_{\infty n} = j_n \circ j_{\infty(n+1)}$. In Lean, D_∞ is **`InverseLimit D P`** and $j_{\infty n}$ is **`limitProjectionToLevel n`**.

Cone. A **cone** over the diagram consists of an **apex** object Y and **legs** $u_n : Y \to D_n$ that agree with the tower: $u_n = j_n \circ u_{n+1}$. A **mediating map into the limit** is a morphism $\{u_\infty : Y \to D_\infty\}$ with $u_n = j_{\infty n} \circ u_\infty$ for all n.

Cocone. A **cocone** over the **same** diagram consists of an apex D' and legs $f_n : D_n \to D'$ in the opposite direction, compatible with **inclusions**:

$$f_n = f_{n+1} \circ i_n$$

(in Lean: **`hf : ∀ n x, (f n) x = (f (n + 1)) ((P n).incl x)`** for **`f n : ScottMap (D n) D'`**). A **mediating map out of the limit** is $\{g : D_\infty \to D'\}$ with $f_n = g \circ i_{n\infty}$; the library name for $i_{n\infty}$ is **`embInf`**.

Name `coconeInf`. cocone + Inf means a cocone whose mediating map has **domain the inverse limit** (`Inf` = inverse limit, **not** a meet / infimum $\sqcap$ in the order). The cocone **legs** are the family **`f n`**; the **Inf** part is where g is defined.

Supremum in the formula. On continuous lattices, a point $x \in D_\infty$ is determined by its coordinates and by directed suprema of approximants. The mediating value $g(x)$ is expressed as a **supremum** $\bigsqcup_n$ over levels of the leg values $(f\,n)(x_n)$—lattice **sup**, not an infimum over n.

Reading Scott's symbols in category-theoretic terms Scott's $f_n : Y \to X_n$ are the **legs of a cone** with apex Y: compatibility is exactly $f_n = j_n \circ f_{n+1}$. His $\{f_\infty : Y \to X_\infty\}$ is the **mediating map into the inverse limit**, assembling a compatible sequence $f_\infty(y) = \langle f_n(y)\rangle$, with factorization $f_n = j_{\infty n} \circ f_\infty$. This paragraph is **not** a cocone (all arrows point **into** the stages, not **out of** them).

For $\langle D_n, P_n\rangle$, X_∞ is **`InverseLimit D P`**. The dual **cocone** story—maps $D_n \to D'$, mediating map **out of** the limit, and **`coconeInf`**—is what Corollary 4.3 formalizes; Scott's displayed f_n are not those legs.

Definition (`coconeInf`) Given **`f : ∀ n, ScottMap (D n) D'`** and **`x : InverseLimit D P`**,

$$\texttt{coconeInf}\,D\,P\,f\,x = \bigsqcup_{n=0}^{\infty} (f\,n)\,(x.1\,n).$$

When **`hf`** holds, **`coconeInf D P f`** is the unique mediating **`ScottMap (InverseLimit D P) D'`** (as **`ScottMap`**, via **`preservesDirectedSup`**).

Theorems in the namespace `coconeInf` The definition **`coconeInf`** sits outside the namespace; the lemmas below are **`coconeInf.apply`**, **`coconeInf.climb`**, and so on.

Theorem (`coconeInf.apply`). *For **`f`** and **`x`**,*

$$\texttt{coconeInf}\,D\,P\,f\,x = \bigsqcup_{n} (f\,n)\,(x.1\,n).$$

Proof. Definition of **coconeInf**. □

Theorem (coconeInf.climb). *If* **hf**, *then for* **n**, **x : D n**, *and* **h : n ≤ m**,

$$(f\,m)\,(\text{embeddingAlongTower}\,D\,P\,h\,x) = (f\,n)\,x.$$

Proof. **Nat.le_induction**: base **embeddingAlongTower.self**, successor **embeddingAlongTower.succ** and **hf**. □

Theorem (coconeInf.descend). *If* **hf**, *for* **h : m ≤ n** *and* **x : D n**,

$$(f\,m)\,(\text{projectionAlongTower}\,D\,P\,h\,x) \le (f\,n)\,x.$$

Proof. **Nat.le_induction**: base **projectionAlongTower.self**, successor **projectionAlongTower.su** **hf**, **incl_retr_le**. □

Theorem (coconeInf.comp_embInf). *If* **hf**, *for* **n**, **x : D n**,

$$\texttt{coconeInf}\;D\,P\,f\,(\text{embInf}\,D\,P\,n\,x) = (f\,n)\,x.$$

Proof. **iComp.of_le** / **iComp.of_ge**, **climb**, **descend**, and **iComp.self**. □

Theorem (coconeInf.preservesDirectedSup). *For every* **f**, ***coconeInf D P f*** *preserves directed suprema.*

Proof. Coordinatewise **limitProjectionToLevel.preservesDirectedSup**, directed sup for each **f n**, **apply**, **iSup_comm**. □

Corollary 4.3: **coconeInf D P f** is the unique mediating cocone **ScottMap**—existence from **comp_embInf**, uniqueness from **inverseLimit.eq_iSup**.

2.5.5 Special inverse systems ✓

So much for a review of inverse limits. In this paper our interest will center on rather special inverse systems and their limits.

2.5.6 Projections along the tower ✓

For an inverse system of continuous lattices $\langle D_n, P_n\rangle$ with $j_n = (P\,n).\text{retr} : D_{n+1} \to D_n$, Scott iterates the j_n but does not introduce a separate symbol for the composite. When $m \le n$, descending from level n to m means applying $j_{n-1}, j_{n-2}, \ldots, j_m$ (dually, Embeddings along the tower climbs with $i_k = (P\,k).\text{incl}$).

Definition (projectionAlongTower). Given **h : m ≤ n**, **projectionAlongTower D P h** is the map $D_n \to D_m$ obtained by recursion on **h**, at each successor step applying **(P k).retr**.

In the namespace **projectionAlongTower** we have

Theorem (self). *For* **h : m ≤ m**, ***projectionAlongTower D P h*** *is the identity on* D_m.

Proof. The recursion for **Nat.leRecOn** at a reflexive proof is **id**. □

Theorem (succ). *If* **h1 : m ≤ n** *and* **h2 : m ≤ n + 1**, *then for all* **z : D (n + 1)**,

$$\text{projectionAlongTower}\,D\,P\,h_2\,z = \text{projectionAlongTower}\,D\,P\,h_1\,(j_n(z)).$$

Proof. Unfold **projectionAlongTower** and **Nat.leRecOn_succ**. □

Theorem (mono). *If `h : m ≤ n` and `x ≤ y` in D_n, then **`projectionAlongTower D P h x ≤ projectionAlongTower D P h y`.*

Proof. Induct on **n** and **h** with **Nat.le_induction**. The base case is **self**. For the successor step, rewrite with **succ** and use monotonicity of **(P k).retr**. □

Theorem (compatible). *If* **y : InverseLimit D P**, *then for every* **n** *and* **h : m ≤ n**,

$$\mathrm{projectionAlongTower}\ D\ P\ h\ (y\,n) = y\,m.$$

Proof. Induct on **n** and **h**. The base is **self**; the successor step uses **succ** and compatibility **(P k).retr (y (k + 1)) = y k**. □

Theorem (retr). *If* **h : m + 1 ≤ n**, *then for all* **x : D n**,

$$j_m\big(\mathrm{projectionAlongTower}\ D\ P\ h\ x\big) = \mathrm{projectionAlongTower}\ D\ P\ h'\ x \quad \text{for the unique } h' : m \le n \text{ with } m{+}1 \le n.$$

Proof. Induct on **n** and **h**, unfolding **succ** and using **self** at the base. □

Theorem (preservesDirectedSup). *If* **h : m ≤ n**, *then* **projectionAlongTower D P h** *preserves directed suprema.*

Proof. Induct on **h**. At **m = n**, **self** gives the identity. For the successor step, **succ** expresses **projectionAlongTower** as a composite of the lower **projectionAlongTower** with **(P k).retr**; apply **ScottMap.preservesDirectedSup_comp** and directed-sup preservation for **(P k).retr**. □

2.5.7 Tower step adjunction ✓

For an inverse system $\langle D_n, P_n \rangle$, fix one index n. Write $i_n = (P\,n).\mathrm{incl} : D_n \to D_{n+1}$ and $j_n = (P\,n).\mathrm{retr} : D_{n+1} \to D_n$ for the continuous lattice projection on that **step** (one rung of the tower, not the composite descent in Projections along the tower).

What an adjunction is (order theory) Two posets and two monotone maps $f : P \to Q$, $g : Q \to P$ form an **adjunction** $f \dashv g$ when comparisons after applying f are equivalent to comparisons after applying g:

$$f(x) \le y \iff x \le g(y) \qquad (x \in P,\ y \in Q).$$

Same question on the left always matches the same question on the right. In Lean this predicate is named **`GaloisConnection`**; "Galois connection" and "adjunction between posets" mean the same thing here. The map on the left (f) is the **left adjoint**, the map on the right (g) the **right adjoint**.

Reading the equivalence for one tower step: embedding $x \in D_n$ into D_{n+1} and comparing to y is the same as comparing x to the retraction $j_n(y) \in D_n$.

Why a projection step is an adjunction A continuous lattice projection is not merely two monotone maps. It satisfies $j_n \circ i_n = \mathrm{id}_{D_n}$ (**`retr_incl`**) and $i_n(j_n(y)) \le y$ for all $y \in D_{n+1}$ (**`incl_retr_le`**). Those two facts are exactly the two directions of the equivalence above:

- If $i_n(x) \le y$, apply monotone j_n and use $j_n(i_n(x)) = x$ to get $x \le j_n(y)$.
- If $x \le j_n(y)$, apply monotone i_n and use $i_n(j_n(y)) \le y$ to get $i_n(x) \le y$.

Without **`incl_retr_le`**, a retraction alone would not prove the second implication in general. The library lemma **`tower_step_galoisConnection`** records the packaged result.

Theorem (`tower_step_galoisConnection`). *For every* ***`n : ℕ`****,* ***`GaloisConnection ((P n).incl) ((P n).retr)`****: for all* ***`x : D n`****,* ***`y : D (n + 1)`****,*

$$i_n(x) \le y \iff x \le j_n(y).$$

Proof. The forward implication applies **`(P n).retr`** monotonically and uses **`retr_incl`**. The reverse uses monotonicity of **`incl`** and **`incl_retr_le`**. □

This adjunction is used when building infima on the inverse limit (see The limit lattice): the right adjoint **`retr`** preserves arbitrary meets.

2.5.8 Embeddings along the tower ✓

For an inverse system of continuous lattices $\langle D_n, P_n\rangle$ with $i_n = (P\,n).\mathrm{incl} : D_n \to D_{n+1}$, Scott iterates the i_n but does not introduce a separate symbol for the composite. When $n \le m$, climbing from level n to m means applying $i_n, i_{n+1}, \dots, i_{m-1}$ (dually, Projections along the tower descends with $j_k = (P\,k).\mathrm{retr}$). Each i_n is the inclusion half of the continuous lattice projection on one **step** of the tower (Tower step adjunction), not the composite climb defined here.

Definition (`embeddingAlongTower`). Given **`h : n ≤ m`**, **`embeddingAlongTower D P h`** is the map $D_n \to D_m$ obtained by recursion on **`h`**, at each successor step applying **`(P k).incl`**.

In the namespace **`embeddingAlongTower`** we have

Theorem (`self`). *For **`h : n ≤ n`**, **`embeddingAlongTower D P h`** is the identity on D_n.*

Proof. The recursion for **`Nat.leRecOn`** at a reflexive proof is **`id`**. □

Theorem (`succ`). *If **`h1 : n ≤ m`** and **`h2 : n ≤ m + 1`**, then for all **`x : D n`**,*

$$\mathrm{embeddingAlongTower}\ D\ P\ h_2\ x = i_m\big(\mathrm{embeddingAlongTower}\ D\ P\ h_1\ x\big).$$

Proof. Unfold **`embeddingAlongTower`** and **`Nat.leRecOn_succ`**. □

Theorem (`succ_left`). *If **`h1 : n ≤ m`** and **`h2 : n + 1 ≤ m`**, then for all **`x : D n`**,*

$$\mathrm{embeddingAlongTower}\ D\ P\ h_2\ (i_n(x)) = \mathrm{embeddingAlongTower}\ D\ P\ h_1\ x.$$

Proof. Unfold **`embeddingAlongTower`** and apply **`Nat.leRecOn_succ_left`**. □

Theorem (`mono`). *If **`h : n ≤ m`** and **`x ≤ y`** in D_n, then **`embeddingAlongTower D P h x ≤ embeddingAlongTower D P h y`.*

Proof. Induct on **`m`** and **`h`** with **`Nat.le_induction`**. The base case is **`self`**. For the successor step, rewrite with **`succ`** and use monotonicity of **`(P k).incl`**. □

Theorem (`le`). *If **`y : InverseLimit D P`** and **`h : n ≤ m`**, then*

$$\mathrm{embeddingAlongTower}\ D\ P\ h\ (y\,n) \le y\,m.$$

Proof. Induct on **m** and **h**. The base is **self**. For the successor step, use **succ**, monotonicity of **(P k).incl**, compatibility **(P k).retr (y (k + 1)) = y k**, and **incl_retr_le**. □

Theorem (preservesDirectedSup). *If* ***h : n ≤ m****, then* ***embeddingAlongTower D P h*** *preserves directed suprema.*

Proof. Induct on **h**. At **n = m**, **self** gives the identity. For the successor step, **succ** expresses **embeddingAlongTower** as a composite of **(P k).incl** with the lower **embeddingAlongTower**; apply **ScottMap.preservesDirectedSup_comp** and directed-sup preservation for **(P k).incl**. □

2.5.9 Coordinates of an embedding ✓

A point of the inverse limit $D_\infty = \text{InverseLimit}\ D\ P$ is a compatible family $(y_m)_{m\in\mathbb{N}}$ with $y_m \in D_m$ and $j_m(y_{m+1}) = y_m$. Scott's embedding $\{i_{n\infty} : D_n \to D_\infty\}$ (Prop. 4.2) is built **coordinate by coordinate**: for fixed n and $x \in D_n$, the m-th component $i_{n\infty}(x)_m$ must be an element of D_m that fits into such a family.

- When $m \geq n$, the only sensible choice is to **climb** from x along the tower of inclusions $i_k = (P\,k).\text{incl}$ — the map Embeddings along the tower **`embeddingAlongTower`**.
- When $m < n$, compatibility with higher coordinates forces the value at m to be obtained by **descending** from x along retractions $j_k = (P\,k).\text{retr}$ — Projections along the tower **`projectionAlongTower`**.

`iComp` is short for Scott's $i_{n\infty}$ **component**: **`iComp D P n x m`** is the m-th coordinate $(i_{n\infty}(x))_m$ (the **`i`** matches Scott's embedding $i_{n\infty}$, **`Comp`** = component at index **`m`**). There is no single tower map $D_n \to D_m$ for all **`m`**: the recipe switches at **`n`** $\leq$ **`m`** vs **`n`** $\not\leq$ **`m`**, and **`iComp`** packages that case split once so **`embInf`** can build **`i_{n\infty}(x)`** as the compatible sequence **`m`** $\mapsto$ **`iComp D P n x m`**.

Definition (`iComp`). For **`n`**, **`x : D n`**, and **`m`**,

$$\texttt{iComp}\,D\,P\,n\,x\,m = \begin{cases} \texttt{embeddingAlongTower}\,D\,P\,h\,x & \text{if } n \le m, \\ \texttt{projectionAlongTower}\,D\,P\,h'\,x & \text{if } n \not\le m, \end{cases}$$

where **`h`** and **`h'`** are the canonical proofs produced from **`n ≤ m`** or **`¬ n ≤ m`**.

In the namespace **`iComp`** we have

Theorem (`of_le`). *If **`h : n ≤ m`**, then **`iComp D P n x m = embeddingAlongTower D P h x`**.*

Theorem (`of_ge`). *If **`¬ n ≤ m`**, then **`iComp D P n x m = projectionAlongTower D P (le_of_lt (not_le.mp h)) x`**.*

Theorem (`self`). *For all **`n`**, **`x : D n`**, **`iComp D P n x n = x`**.*

Proof. **`of_le`** and **`embeddingAlongTower.self`**. □ (This is the identity **`j_{\infty n} ∘ i_{n\infty} = \mathrm{id}`** at the coordinate level.)

Theorem (`compatible`). *For every **`n`**, **`x : D n`**, the sequence **`fun m => iComp D P n x m`** satisfies the inverse-limit compatibility laws.*

Proof. Case split on **`n ≤ m`**, **`n ≤ m + 1`**, and **`m + 1 ≤ n`**; the delicate middle case **`n = m + 1`** uses **`projectionAlongTower.succ`** and **`self`**, the general descent case uses **`projectionAlongTower.retr`**. □

Theorem (`incl_le`). *If **`y : InverseLimit D P`**, then for all **`n`**, **`m`**, **`iComp D P n (y.1 n) m ≤ y.1 m`**.*

Proof. If **`n ≤ m`**, **`embeddingAlongTower.le`**; if **`n ≰ m`**, the coordinate equals **`y.1 m`** by **`projectionAlongTower.compatible`**. □

Theorem (`preservesDirectedSup`). *For fixed **`n`**, **`m`**, **`fun x => iComp D P n x m`** preserves directed suprema.*

Proof. **`by_cases`** on **`n ≤ m`**, then rewrite to **`embeddingAlongTower`** or **`projectionAlongTower`**. □

Theorem (`monotone`). *For fixed **`n`**, **`m`**, **`fun x => iComp D P n x m`** is monotone.*

Proof. From **`preservesDirectedSup`** via **`preservesDirectedSup_monotone`**. □

Use. Embeddings into the limit packages ⟨**`iComp D P n x, iComp.compatible D P n x`**⟩ as **`embInf.fun D P n x : InverseLimit D P`** — Scott's $i_{n\infty}(x)$.

2.5.10 Embeddings into the limit ✓

For an inverse system of continuous lattices $\langle D_n, P_n \rangle$, write $D_\infty = \mathrm{InverseLimit}\, D\, P$ for the limit lattice of compatible sequences $(y_m)_{m \in \mathbb{N}}$. Scott's **inverse embedding** at level n is a map $\{i_{n\infty} : D_n \to D_\infty\}$ that sends $x \in D_n$ to the point of D_∞ whose coordinates are determined by climbing or descending the tower from x at index n.

Definition (`embInf`). For each $n \in \mathbb{N}$, **`embInf D P n`** is the **Scott map** $D_n \to D_\infty$ whose underlying function is **`embInf.fun D P n`** and whose Scott continuity is proved from directed-sup preservation on that function.

Definition (`embInf.fun`). For $n \in \mathbb{N}$ and $x \in D_n$, **`embInf.fun D P n x`** is the element of **`InverseLimit D P`** whose m-th coordinate is **`iComp D P n x m`**—equivalently, the compatible sequence $(i_{n\infty}(x)_m)_{m \in \mathbb{N}}$ in Scott's notation.

In the namespace **`embInf`** we have

Theorem (`coe`). *For all* ***`n`, `x : D n`****, the coordinate function of* ***`embInf.fun D P n x`*** *is* ***`iComp D P n x`****:*

$$(\mathrm{embInf.fun}\, D\, P\, n\, x)_m = \mathrm{iComp}\, D\, P\, n\, x\, m.$$

Proof. Definition of **`embInf.fun`** as a subtype of **`iComp`** with compatibility. □

Theorem (`monotone`). *For each* ***`n`****, the map* ***`embInf.fun D P n : D_n → D_\infty`*** *is monotone (with respect to the lattice orders on D_n and D_∞).*

Proof. Reduce to comparisons coordinatewise via **`Subtype.coe_le_coe`**; at each **`m`** apply **`iComp.monotone`**. □

Theorem (`preservesDirectedSup`). *For each* ***`n`****,* ***`embInf.fun D P n`*** *preserves directed suprema in D_n.*

Proof. For a directed set $S \subseteq D_n$, compare suprema in D_∞ using **`coe_sSup_of_directed`** on the image **`embInf.fun D P n " S`**, then rewrite each coordinate with **`iComp.preservesDirectedSup`**. □

Theorem (`succ`). *For all* ***`n`, `x : D_n`****,*

$$i_{(n+1)\infty}\,(i_n(x)) = i_{n\infty}(x),$$

formally **`embInf D P (n + 1) ((P n).incl x) = embInf D P n x`**.

Proof. Compare coordinates **`m`** by case analysis on **`n ≤ m`**, **`n + 1 ≤ m`**, and **`m < n`**; use the computation laws for **`iComp`**, **`embeddingAlongTower`**, and **`projectionAlongTower`**. □

Theorem (`le_succ`). *If* ***`y : InverseLimit D P`****, then for every* ***`n`****,*

$$i_{n\infty}(y_n) \le i_{(n+1)\infty}(y_{n+1}).$$

Proof. Rewrite with **`succ`** at **`x = y n`**, then apply **`monotone`** for index **`n + 1`** and **`(P n).incl_retr_le`** with compatibility **`(P n).retr (y (n + 1)) = y n`**. □

Theorem (`family_directed`). *If* **`y : InverseLimit D P`**, *the set* $\{\, i_{n\infty}(y_n) \mid n \in \mathbb{N} \,\}$ *is directed in* D_∞.

Proof. **`le_succ`** gives a monotone sequence in **`n`**; apply **`directedOn_range`** and **`monotone_nat_of_le_succ`**. □

2.5.11 Order on the inverse limit ✓

A point of the inverse limit $D_\infty = \mathrm{InverseLimit}\, D\, P$ is a compatible sequence $(x_m)_{m\in\mathbb{N}}$ with $x_m \in D_m$. The **product** order on all sequences (y_m) would declare $x \le y$ when $x_m \le y_m$ at every index; the limit inherits that comparison because D_∞ is a subtype of the product.

Definition (`inverseLimitLE`). For **`x`**, **`y : InverseLimit D P`**,

$$\texttt{inverseLimitLE}\; D\, P\, x\, y \iff \forall n,\; x_n \le y_n$$

(coordinatewise $\le$ in each stage lattice D_n; in Lean, **`x.1 n ≤ y.1 n`**).

In the namespace **`inverseLimitLE`** we have

Theorem (`refl`). *For all **`x`**, **`inverseLimitLE D P x x`.*

Proof. **`le_refl`** at each coordinate. □

Theorem (`trans`). *If **`inverseLimitLE D P x y`** and **`inverseLimitLE D P y z`**, then **`inverseLimitLE D P x z`.*

Proof. **`le_trans`** coordinatewise. □

Theorem (`antisymm`). *If **`inverseLimitLE D P x y`** and **`inverseLimitLE D P y x`**, then **`x = y`.*

Proof. **`Subtype.ext`** and **`funext`**: equal coordinates give **`le_antisymm`** at each **`n`**. □

Use. Proofs that a map into D_∞ is monotone (for example **`embInf.monotone`**) rewrite with **`Subtype.coe_le_coe`** and compare coordinates in D_m at each **`m`**.

2.5.12 Strict order on the inverse limit ✓

On the inverse limit $D_\infty = \mathrm{InverseLimit}\, D\, P$, the coordinatewise order Order on the inverse limit **`inverseLimitLE`** is the natural $\leq$. The **strict** comparison is the usual one for a partial order: below in $\leq$ but not above.

Definition (`inverseLimitLT`). For **`x`**, **`y : InverseLimit D P`**,

$$\texttt{inverseLimitLT}\, D\, P\, x\, y \iff \texttt{inverseLimitLE}\, D\, P\, x\, y \wedge \neg\, \texttt{inverseLimitLE}\, D\, P\, y\, x.$$

Equivalently: $x \leq y$ coordinatewise and it is **not** the case that $y \leq x$ coordinatewise (so some coordinate is strictly below, or the sequences differ).

In the namespace **`inverseLimitLT`** we have

Theorem (`iff_LE_not_GE`). *For all* ***`x`****,* ***`y`****,*

$$\texttt{inverseLimitLT}\, D\, P\, x\, y \iff \texttt{inverseLimitLE}\, D\, P\, x\, y \wedge \neg\, \texttt{inverseLimitLE}\, D\, P\, y\, x.$$

Proof. Definition of **`inverseLimitLT`**. □

Coordinate infima ✓ For $S \subseteq D_\infty = \mathrm{InverseLimit}\, D\, P$, a natural candidate for an infimum in D_∞ is built **coordinate by coordinate**: at index n, take the infimum in D_n of the n-th coordinates of points in S.

Definition (`inverseLimitSInfCoe`). For **`S : Set (InverseLimit D P)`**,

$$(\mathtt{inverseLimitSInfCoe}\, D\, P\, S)_n = \inf\{\, x_n \mid x \in S \,\}$$

in D_n (Lean: **`sInf ((fun x => x.1 n) '' S)`**).

In the namespace **`inverseLimitSInfCoe`** we have

Theorem (apply). *For all **S**, **n**, the **n-th coordinate of** `inverseLimitSInfCoe D P S`** is that stage infimum:*

$$\texttt{inverseLimitSInfCoe}\, D\, P\, S\, n = \inf\{\, x_n \mid x \in S \,\}.$$

Proof. Definition of **`inverseLimitSInfCoe`**. □

Complete lattice on the inverse limit ✓ Write $D_\infty = \mathrm{InverseLimit}\, D\, P$ with the coordinatewise order from **`inverseLimitLE`**. A **complete lattice** is a partially ordered set in which **every** subset S has a **greatest lower bound** (infimum, written $\inf S$ or $\bigwedge S$) and a **least upper bound** (supremum, $\sup S$ or $\bigvee S$).

What `sInf`** is.** For $S \subseteq D_\infty$, **`sInf S`** is Lean's notation for that **set infimum** in D_∞: the **largest** element $y \in D_\infty$ such that $y \le x$ for every $x \in S$. Concretely it is the compatible sequence whose n-th coordinate is $\inf\{\, x_n : x \in S \,\}$ in the stage lattice D_n (see **`instInfSet`** and **`instInfSet.isGLB_sInf'`**).

Theorem (`instCompleteLattice`). *D_∞ is a complete lattice.*

Proof. We already have a partial order on D_∞ and, for each $S \subseteq D_\infty$, an element **`sInf S`** that is the **greatest lower bound** of S (**`instInfSet.isGLB_sInf'`**). A standard order-theoretic fact is then enough: **if every subset has an infimum, the poset is a complete lattice**. Define suprema from infima by the usual dual recipe— for $S \subseteq D_\infty$, take the infimum of the set of **upper bounds** of S:

$$\sup S \;=\; \inf\{\, u \in D_\infty \mid \forall x \in S,\ x \le u \,\}.$$

That infimum exists by the construction above, and it is the least upper bound of S. Finite meets and joins agree with this inf / sup. Lean packages this construction as **`instCompleteLattice`**, applying Mathlib's **`completeLatticeOfInf`** to the partial order and the **`isGLB_sInf'`** proof. □

Definition (`instCompleteLattice`). **`instCompleteLattice D P`** is the **`CompleteLattice`** instance on **`InverseLimit D P`** obtained in this way (one declaration in **`instCompleteLattice.lean`**).

`instCompleteLattice.lean`

```
module

public import DomainTheory.ContinuousLattice.InverseLimits.instInfSet

@[expose] public section

namespace DomainTheory.ContinuousLattice

end InverseLimit

end DomainTheory.ContinuousLattice
```

Directed suprema are coordinatewise ✓ Write $D_\infty = \mathrm{InverseLimit}\ D\ P$ with the coordinatewise order. D_∞ is a **complete lattice**, so every subset $S \subseteq D_\infty$ has a **least upper bound** (supremum). Lean writes that set supremum as **`sSup S`**; in ordinary notation it is $\sup S$ or $\bigvee S$— the **smallest** $u \in D_\infty$ with $x \le u$ for all $x \in S$.

A set $S \subseteq D_\infty$ is **directed** (upward) when for every $x, y \in S$ there exists $z \in S$ with $x \le z$ and $y \le z$. Each stage lattice D_n is a complete lattice, so for nonempty S the coordinate set $\{\, x_n \mid x \in S \,\} \subseteq D_n$ has a supremum there; when S is directed, that coordinatewise family is directed in D_n as well.

Theorem (`coe_sSup_of_directed`). *Suppose $S \subseteq D_\infty$ is **nonempty** and **directed**. For every $n \in \mathbb{N}$, the n-th coordinate of $\sup S$ equals the supremum taken in D_n:*

$$\big(\sup S\big)_n \;=\; \sup\{\, x_n \mid x \in S \,\}.$$

Proof. Define $f(n) \in D_n$ by $f(n) = \sup\{\, x_n \mid x \in S \,\}$ for each $n \in \mathbb{N}$.

Compatibility. A point of D_∞ must satisfy $j_n(f(n+1)) = f(n)$ for each projection $j_n = (P_n).\mathrm{retr}$. Fix n. The set $\{\, x_{n+1} \mid x \in S \,\}$ is a directed nonempty subset of D_{n+1}, so $(P_n).\mathrm{retr}$ preserves its supremum. Rewriting that preservation with the compatibility laws $j_n(x_{n+1}) = x_n$ for $x \in S$ shows $j_n(f(n+1)) = f(n)$.

Least upper bound. Let $p \in D_\infty$ be the compatible sequence f. Every $x \in S$ has $x_n \le f(n)$ for each n, so $x \le p$ in the coordinatewise order. If $b \in D_\infty$ is an upper bound of S, then for each n and each $x \in S$, $x_n \le b_n$, hence $f(n) \le b_n$ and $p \le b$. Thus $p = \sup S$.

Uniqueness of least upper bounds identifies p with **`sSup S`**. □

Use. When a proof compares $\sup$ in D_∞ with data in some D_n, it rewrites $\sup S$ with this theorem so the n-th coordinate is a supremum inside D_n (for example in **`embInf.preservesDirectedSup`**).

2.5.14 Topology of the inverse limit ✓

Write $D_\infty = \mathrm{InverseLimit}\, D\, P$. Scott topologizes each stage lattice D_n; on **all** sequences $(x_n)_{n\in\mathbb{N}}$ the product topology is the Tychonoff product of those Scott topologies. The **inverse limit topology** on D_∞ is the subspace topology inherited from that product: open sets in D_∞ are exactly the intersections of product opens with the set of **compatible** sequences.

Definition (`inverseLimitTopology`). `inverseLimitTopology D P` is

$$\mathcal{T}_\infty \;=\; \Big\{ U \cap D_\infty \;\Big|\; U \text{ open in } \prod_{n\in\mathbb{N}} (D_n,\ \text{Scott}) \Big\},$$

implemented as `TopologicalSpace.induced Subtype.val` from the Pi topology with `scottTopologicalSpace` on each factor.

In the namespace `inverseLimit` we have

Theorem (`coordinate_continuous`). *For each* `n`*, the coordinate map* `x ↦ x_n` *is continuous from* `inverseLimitTopology` *to Scott on* D_n.

Proof. Open sets in the product are detected coordinatewise; preimages factor through `continuous_apply`. □

Theorem (`t0Space`). $(D_\infty, \mathcal{T}_\infty)$ *is* T_0.

Proof. `Subtype.val` is an embedding into a product of T_0 spaces. □

Theorem (`specializationPreorder_iff`). *For* `x, y : InverseLimit D P`*, specialization preorder in* `inverseLimitTopology` *agrees with coordinatewise* $\le$*:*

$$x \preceq y \iff x \le y.$$

Proof. Compare `specializes` along the embedding into the product; at each index use Scott specialization on D_n. □

Theorem (`isInjectiveSpace`). *If each* `D n` *is a continuous lattice, then* $(D_\infty, \mathcal{T}_\infty)$ *is an* ***injective space*** *(Scott's §1 notion).*

Proof. Given a continuous `f : X → D_\infty` from a compact Hausdorff `X`, read coordinates `f_n`, extend each by `scottExtend`, check compatibility with `lemma_3_9`, assemble the extension map into D_∞, and compare on coordinates with `scottExtend_eq_of_continuous`. □

Theorem (`scottTopology_eq_induced_pi`). *When each stage is a continuous lattice, the* ***Scott topology*** ***`scottTopologicalSpace`*** *on* D_∞ ***equals*** ***`inverseLimitTopology`***.

Proof. **`isInjectiveSpace`** and **`specializationPreorder_iff`** pin down the Scott topology on an injective space; apply **`continuousLattice_scottTopology_of_injective`**. □

Theorem (`eq_iSup`). *Every* ***`x : InverseLimit D P`*** *is the supremum of its approximants along embeddings:*

$$x = \bigvee_{n \in \mathbb{N}} i_{n\infty}(x_n).$$

Proof. The family $\{\, i_{n\infty}(x_n) \mid n \in \mathbb{N} \,\}$ is directed; compare coordinates using **`coe_sSup_of_directed`**, **`embInf.family_directed`**, and **`iComp`**. □

In the namespace **`inverseLimitTopology`** we have

Theorem (`limitProjectionToLevel`). *Each* ***`limitProjectionToLevel n`*** *($j_{\infty n}$) is continuous.*

Proof. Same as **`coordinate_continuous`**. □

Theorem (`embInf`). *If stages are continuous lattices, each* ***`embInf n`*** *($i_{n\infty}$) is continuous into* ***`inverseLimitTopology`***.

Proof. Rewrite with **`scottTopology_eq_induced_pi`**; use the **`ScottMap`** instance on **`embInf`**. □

Theorem (`coconeInf`). *Under the same hypothesis,* ***`coconeInf f`*** *is continuous from* ***`inverseLimitTopology`***

Proof. Again identify Scott with **`inverseLimitTopology`**, then **`PreservesDirectedSup.continuous_of`** and **`coconeInf.preservesDirectedSup`**. □

2.5.15 Proposition 4.1 ✓

4.1 Proposition. Let $\langle D_n, j_n\rangle_{n=0}^{\infty}$ be an inverse system of continuous lattices where each $j_n : D_{n+1} \to D_n$ is a projection. Then the inverse limit space D_∞ is also a continuous lattice.

Proof: We need only show that D_∞ as a T_0-space is injective. So suppose $\{f_\infty : X \to D_\infty\}$ is given and $X \subseteq Y$. Define $f_n : X \to D_n$ by $f_n = j_{\infty n} \circ f_\infty$. Let $\bar{f} * n : Y \to D_n$ be the maximal extension of f_n according to 3.8. Now we can see the point of Lemma 3.9: by this construction we guarantee that $\bar{f}n = j_n \circ \bar{f}n + 1$. Hence the required $\bar{f} * \infty : Y \to D_\infty$ exists. □

I do not know at the time of writing whether this theorem on inverse limits of continuous lattices extends to sequences where, say, the j_n are only retractions. Fortunately, sufficiently many projections exist to make this construction useful. Note that by reference to the product space construction of D_∞, its lattice ordering is given simply by the relation:

$$x \sqsubseteq y \quad \text{iff} \quad x_n \sqsubseteq y_n \text{ for all } n.$$

2.5.16 Proposition 4.2 ✓

4.2 Proposition. Let $\langle D_n, j_n\rangle_{n=0}^{\infty}$ and D_∞ be as in 4.1. Then the maps $j_{\infty\{n} : D_\infty \to D_n\}$ are projections.

Proof: The projections $j_n : D_{n+1} \to D_n$, as we know, have their uniquely determined inverses $i_n : D_n \to D_{n+1}$. We can define $\{i_{n\infty} : D_n \to D_\infty\}$ by the equation:

$$i_{n\infty}(x) = \langle y_m\rangle_{m=0}^{\infty}$$

where

$$y_m = \begin{cases} j_m(y_{m+1}) & \text{if } m < n, \\ x & \text{if } m = n, \\ i_m(y_{m-1}) & \text{if } m > n. \end{cases}$$

The proof that $i_{n\infty}$ and $j_{\infty n}$ form a projection is now an easy computation. □

Definition (`limitLevelProjection`). For **`n : ℕ`**, **`limitLevelProjection D P n`** is the **continuous lattice projection** from D_n to $D_\infty = \mathrm{InverseLimit}\ D\ P$ with

- **`incl`** $= i_{n\infty} =$ **`embInf D P n`**
- **`retr`** $= j_{\infty n} =$ **`limitProjectionToLevel D P n`**

The retraction law **`retr_incl`** is **`iComp.self`** at index **`n`**; **`incl_retr_le`** is coordinatewise **`iComp.incl_le`**.

Theorem (`proposition_4_2`). *For every* ***`n`****, there is a continuous lattice projection from D_n to D_∞ whose retraction is $j_{\infty n}$ and whose inclusion is $i_{n\infty}$—equivalently,* ***`Nonempty (ContinuousLatticeProjection (D n) (InverseLimit D P))`****, witnessed by* ***`limitLevelProjection D P n`****.*

Proof. **`limitLevelProjection D P n`**. □

One should note also the recursion equation:

$$i_{n\infty} = i_{(n+1)\infty} \circ i_n.$$

These maps also make it possible to state this useful equation:

$$x = \bigsqcup_{n=0}^{\infty} i_{n\infty}(x_n),$$

where $x \in D_\infty$. It is easy to check that this is a monotone lub, and so we can say each $x \in D_\infty$ is the limit of its projections x_n. In fact, from what we know about projections, x_n is the best possible approximation to x in the space D_n.

2.5.17 Corollary 4.3 ✓

4.3 Corollary. Let the spaces be as in 4.1 and 4.2. Let D' be any complete lattice and suppose continuous functions $f_n : D_n \to D'$ are given so that $f_n = f_{n+1} \circ i_n$. Then we can define $\{f_\infty : D_\infty \to D'\}$ by the equation:

$$f_\infty(x) = \bigsqcup_{n=0}^{\infty} f_n(x_n)$$

for $x \in D_\infty$, and we have $f_n = f_\infty \circ i_{n\infty}$. □

The import of this last result is that within the category of complete lattices, the space D_∞ is not only the inverse limit of the D_n, but it is also the *direct* limit. (One system of spaces here uses the j_n as connecting maps, the other the i_n.) This is the algebraic result that lies at the heart of our main result about inverse limits of function spaces.

Turning to function spaces, let $D = D_0$ be a given continuous lattice. As we have seen in 3.13, there are many ways of making D_0 a projection of $D_1 = [D_0 \to D_0]$. Choose one such given by a pair i_0, j_0. Define recursively:

$$D_{n+1} = [D_n \to D_n]$$

and introduce the pairs i_{n+1}, j_{n+1} making D_{n+1} a projection of D_{n+2} by the method of 3.7. Specifically we shall have for $x \in D_{n+1}$ and $x' \in D_{n+2}$:

$$i_{n+1}(x) = i_n \circ x \circ j_n,$$

$$j_{n+1}(x') = j_n \circ x' \circ i_n.$$

Since these spaces are more than continuous lattices being function spaces, it is interesting to note that the maps i_n preserve function value as an algebraic operation as follows:

$$i_n(f(x)) = i_{n+1}(f)(i_n(x)),$$

where $x \in D_n$ and $f \in D_{n+1}$. Thus in passing to the limit space D_∞ something of functional application must also be preserved. The precise result shows that indeed D_∞ becomes its own function space.

Theorem 4.4 4.4 Theorem. *The inverse limit D_∞ of the recursively defined sequence $\langle D_n, j_n\rangle_{n=0}^{\infty}$ of function spaces is not only a continuous lattice, but it is also homeomorphic to its own function space $[D_\infty \to D_\infty]$.*

Proof: We can write down directly the pair of maps i_∞, j_∞ that provide the homeomorphism:

$$i_\infty(x) = \bigsqcup_{n=0}^{\infty}(i_{n\infty} \circ x_{n+1} \circ j_{\infty n}),$$

$$j_\infty(f) = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(j_{\infty n} \circ f \circ i_{n\infty}).$$

Note that these formulae are simply generalizations at the limit for the formulae we used to define i_n, j_n in the first place. Thus it is not surprising that they would provide a projection of $[D_\infty \to D_\infty]$ upon D_∞. Indeed we can compute out $j_\infty(i_\infty(x))$, noting that all the lubs are monotone and that a double monotone limit can always be replaced by a single one in view of the continuity of the operations involved, obtaining

$$j_\infty(i_\infty(x)) = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(j_{\infty n} \circ i_{n\infty} \circ x_{n+1} \circ j_{\infty n} \circ i_{n\infty}) \quad = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(x_{n+1}) = x.$$

In the converse order the calculation is only a bit more complicated. The idea is that since all the functions f are continuous and since the elements x are the limits of their approximations, then each f is actually completely determined by its

In the converse order the calculation is only a bit more complicated. The idea is that since all the functions f are continuous and since the elements x are the limits of their approximations, then each f is actually completely determined by its sequence of restrictions $j_{\infty n} \circ f \circ i_{n\infty} \in D_{n+1}$. This simple idea can be made more precise with the aid of a lemma about D_∞, which allows us in certain cases to recognize projections from limits.

Lemma 4.5 **4.5 Lemma.** Suppose for each n we have $u_{(n+1)} \in D_{n+1}$ and we let:

$$u = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(u_{(n+1)}).$$

Then if

$$j_{n+1}(u_{(n+2)}) = u_{(n+1)}$$

for each n, we can conclude that:

$$j_{\infty(n+1)}(u) = u_{(n+1)}.$$

Proof: If the sequence $u_{(n+1)}$ satisfies the recursion, then the limit defining u is monotonic. Therefore by continuity of projection it suffices to prove that

$$j_{\infty(n+1)}(i_{(m+1)\infty}(u_{(m+1)})) = u_{(n+1)}$$

for all $m \geqslant n$. This is obvious for $m = n$, and it can be readily proved by induction for larger m using the various recursion equations. (Properly speaking the induction is done on the quantity $(m - n)$ using both n and m as variables.) $\square$

Proof of 4.4 concluded **Proof of 4.4 concluded:** The lemma applies at once to our calculation, for we find:

$$i_\infty(j_\infty(f)) = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}\circ f\circ i_{n\infty}\circ j_{\infty n}) \quad = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n})\circ f\circ \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}).$$

Here we have just applied the continuity of f to be able to confine the lub on the right. But now by the remark following 4.2, we note the functional equation:

$$\mathrm{id} = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}),$$

and the proof that i_∞ and j_∞ are inverse to one another is complete. □

2.5.19 The functorial form ✓

We can explain the idea of this proof in other terms using a suggestion made to me by F. W. Lawvere. Consider the category of

We can explain the idea of this proof in other terms using a suggestion made to me by F. W. Lawvere. Consider the category of continuous lattices and projections. In that category our D_∞ is, as we have remarked, both a *direct* and an *inverse* limit. Note too that with regard to projections $[D \to D']$ is a *functor*, for we can also define $[j \to j']$ when the maps are projections. In this language our particular inverse system is defined by the recursion:

$$D_{n+1} = [D_n \to D_n] \quad \text{and} \quad j_{n+1} = [j_n \to j_n],$$

where D_0 and j_0 are given in advance. Now the function space construction is continuous in its two arguments, turning an inverse limit on the right into an inverse limit and a direct limit on the *left* also into an *inverse* limit. A repeated limit can be made into a simple limit, so we can write:

$$D_\infty = \varprojlim \langle D_n, j_n \rangle_{n=0}^{\infty} \quad = \varinjlim \langle D_n, i_n \rangle_{n=0}^{\infty}$$

and

$$[D_\infty \to D_\infty] = \varprojlim \langle [D_n \to D_n], [j_n \to j_n] \rangle_{n=0}^{\infty} \quad = \varprojlim \langle D_{n+1}, j_{n+1} \rangle_{n=0}^{\infty} = D_\infty \quad \textit{(up to isomorphism).}$$

A full checking of the details involved would not make the argument appreciably simpler over the more "element-by-element" argument I have presented. In fact, the proofs are actually the same. But thinking of the result in terms of properties of functors does seem to isolate very well the essential idea and to show how simple it is.

One must only add here a note of caution: the proper choice of category must be done with care. Thus it seems to me that the use of projections rather than arbitrary continuous maps is necessary.

Inasmuch as I have not checked all details in this form, I hope what I say is correct.

2.5.20 Application ✓

Since we have shown $[D_\infty \to D_\infty]$ to be homeomorphic to D_∞, we can begin to regard them as the same. In particular there ought to be some function space structure to transfer to D_∞. This can be done by defining functional application for any elements $x, y \in D_\infty$ by the equation:

$$x(y) = \bigsqcup_{n=0}^{\infty} i_{n\infty}(x_{n+1}(y_n)).$$

Similarly we can define λ-abstraction on continuous expressions:

$$\lambda x.[\ldots x \ldots] = j_\infty(\lambda\{x : D_\infty\}.[\ldots x \ldots]),$$

and in this way D_∞ becomes a model for the λ-calculus of Church and Curry. The model-theoretic and proof-theoretic aspects of this result will be explained in another paper ([19]).

2.5.21 Two projections ✓

Suppose we were to start with the least, non-trivial lattice $0 = \top, \bot$ for D_0. Now $D_1 = [0 \to 0]$ has exactly three elements and there are just two ways of defining a projection $j_0 : D_1 \to D_0$. They are illustrated in the figure:

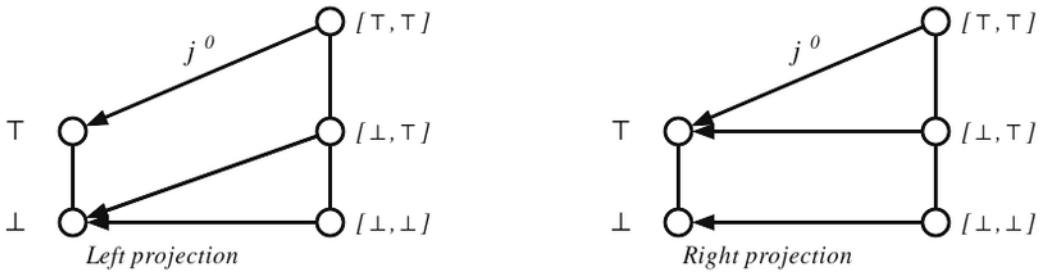

Figure 19: Two j0 projections; D0 on rows 2-3; arrows touch circles.

Hence our construction gives two limit spaces D_∞ and $D' * \infty$. Are they the same? No, they are not. It can be shown, for example, that the $\top$ of $D * \infty$ is *isolated* (that is, $\top \ll \top$), while the same is not true of $D' * \infty$. More interestingly, David Park has proved that the fixed-point operator fix mentioned in 3.14 has algebraic properties in $D * \infty$ quite different from those in $D' * \infty$. By algebraic here, we of course have reference to the functional algebra embodied in the application operation $x(y)$ defined on these limit spaces. Note, by the way, that in view of our isomorphism result we can regard fix (or any other similar continuous function for that matter) as an element of $D * \infty$. This makes the "algebra" of D_∞ quite a rich field for study.

2.5.22 Embedding every space ✓

The reader will have surely remarked that by virtue of 1.5, every T_0-space X whatsoever can be embedded as a subspace in a D_∞. Besides this all the continuous functions on X (oh, into D_∞, say) can be extended to D_∞; whence they can be regarded as *elements* of D_∞. Thus we have been able to embed not only the topology of X into D_∞ but also all of the continuous function theory over X. So far this is only a "logical" construction. For more interesting "mathematical" results we shall have to investigate whether any useful theorems about the usual function spaces $[X \to X]$ can be obtained with the aid of D_∞. This method can easily be employed for real- or complex-valued continuous functions, though it seems more oriented toward pointwise convergence than anything else. Still, there seems to be a chance it might be useful—especially if one wished to consider continuous *operators* on function spaces.

2.5.23 Other functors ✓

The idea of forming the limit space can also be applied to *other* functors besides $[D \to D]$. Thus instead of solving the "equation"

$$D = [D \to D]$$

as we have done with the D_∞ construction, we could also solve:

$$V = T + [V \times V] + [V + V] + [V \to V],$$

for example. Here $T = \bot, 0, 1, \top$ is the four-element lattice with 0 and 1 as incomparable elements. By $[V \times V]$ and $[V \to V]$ we understand the usual Cartesian product and function space construction. The $+$ operator, on the other hand works only in the category of lattices with $\top$ as an isolated element. It is defined so as to make:

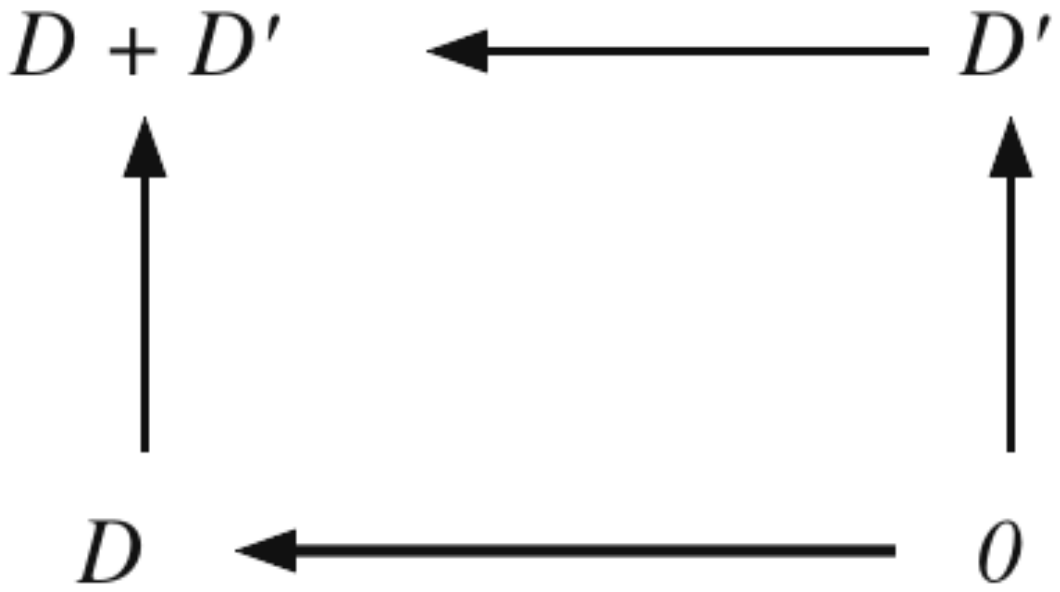

Figure 20: Push-out square: D and D prime map up into D plus D prime, and 0 maps left to D and up to D prime.

a push-out diagram, where the maps from 0 are meant to match $\bot$ with $\bot$ and $\top$ with $\top$. The point of requiring $\top$ to be isolated is that both D and D' become projections of $D + D'$. This construction, though not quite a disjoint union, has many properties in common with that operation on spaces. In particular, if we consider the category with projections as maps, the construction

$$\mathbb{F}(D) = T + [D \times D] + [D + D] + [D \to D]$$

is a *functor*. Furthermore, we can project $\mathbb{F}(T)$ onto T in an obvious way, thereby setting things up for an inverse limit construction:

$$V = \varprojlim \langle \mathbb{F}^n(T), j_n \rangle_{n=0}^{\infty}.$$

The resulting continuous lattice satisfies the desired equation up to isomorphism.

2.5.24 Subspaces of a limit ✓

The space V constructed in the way just indicated is very rich in subspaces. To see this, consider the space $\mathcal{J}_V$ of proper projections j where $j(\top) = \top$. As in 3.12 this is a complete lattice. Now that $[V \times V]$ and $[V + V]$ and $[V \to V]$ are regarded as *subspaces* of this "universe" V itself, we can easily define *continuous operations*

$$(j \times k)\ ,\ (j + k)\ ,\ \text{and}\ (j \to k)$$

on the projections obtaining again elements of $\mathcal{J}_V$. The projections so obtained correspond to the indicated constructions of subspaces, of course. (Indeed, if we had the time and space, we could show that $\mathcal{J}_V$ becomes a very interesting category). There will be a particular

projection t corresponding to T, and reason for doing all this is to show that the existence of subspaces of V can now be established by solving equations in $\mathcal{J}_V$. For example, by the fixed-point construction we could find a $j \in \mathcal{J}_V$ such that

$$j = t + (t \times j) + ((j \times j) \to j).$$

The range of j would then be a subspace $W \subseteq V$ such that W solves the equation:

$$W = T + [T \times W] + [[W \times W] \to W].$$

And these are only a few examples: simultaneous equations are possible, and many other operators are waiting for discovery and application.

2.6 Correction ✓

Correction (Added March, 1972). Robin Milner has pointed out to me that there is an error in the remark in the paragraph immediately preceding Proposition 2.5. I was mistaken in saying that if D is a T_0-space which becomes a complete lattice under its induced partial ordering, then every set open in the given topology is also open in the induced topology. There are many counterexamples to this statement. Let D be any complete lattice. There are two extreme T_0-topologies which will induce the given partial ordering. The smallest such topology has as a sub-base for its open sets those sets of the form:

$$\{x \in D : x \not\sqsubseteq y\}.$$

These sets are easily proved to be open in any T_0-topology which induces the partial ordering. At the other extreme consider sets of the form:

$$\{x \in D : y \sqsubseteq x.\}$$

Such sets will give a base for a T_0-topology that is the maximal topology inducing the given partial ordering. Clearly they need not be open in the induced lattice topology; in particular, they may well fail

to satisfy conditions (ii) on open sets. To make the remark in question correct, we must thus suppose that the given T_0-topology is *contained within* the induced lattice topology. The equation given in the paragraph indicated will then be a sufficient condition for the two topologies to be identical.

The remark was employed in the proof of three different propositions: 2.9, 2.10, and 3.3. In the case of 2.9 one must verify that the product topology is contained within the lattice topology. This need only be done for the basis for the product topology, and for such basic open sets the result needed is obvious. In the case of proposition 2.10 the question concerns a relationship between the topologies of a space and a subspace; the spaces in question are also lattices. Note in passing that a lub in the subspace is generally *larger* in the partial ordering than the corresponding lub relative to the whole space. This puts the inequalities in the wrong direction, and so it is not immediate that a relativized open set for the subspace is open in the lattice topology of the subspace. However, in this case we can appeal to the continuous retraction. Recall that the relativized open sets of the kind that we used in the proof of 2.10 are of the form:

$$U = \{z \in D : x < z\} .$$

Suppose then that S is a directed set, and that using the lub in the sense of D we have

$$\bigsqcup S \in U .$$

Referring back to the proof of 2.10 we know that ($S' = S \subseteq D$, but $\bigsqcup S'$ is the join computed in the ambient lattice D')

$$j(\bigsqcup S') = \bigsqcup S ,$$

which means that

$$x < j(\bigsqcup S') .$$

From this it follows that

$$x < j(z), \text{ some } z \in S .$$

Now $j(z) = z$, and we have what we need. This argument suffices only for a special type of open sets; but these open sets form a base for the topology, and so the argument is quite general.

Turning now to the proof of theorem 2.3 we note that the topology on the function space is simply the *relativized* product topology. There is no difficulty with lubs in this case, because, as we showed in the proof of that theorem, all lubs are calculated pointwise. Thus, it is easy to verify now that the sets open in the product topology are also open in the lattice topology.

3 Datatypes as Lattices (1976) ✓

Dependencies. Each box is one section. Lean ownership is by topic folder. The arrowhead is on the section that imports; the number is how many direct imports. Only paper-forward edges are shown (a later section importing an earlier one). An arrow already implied by a longer path is left out.

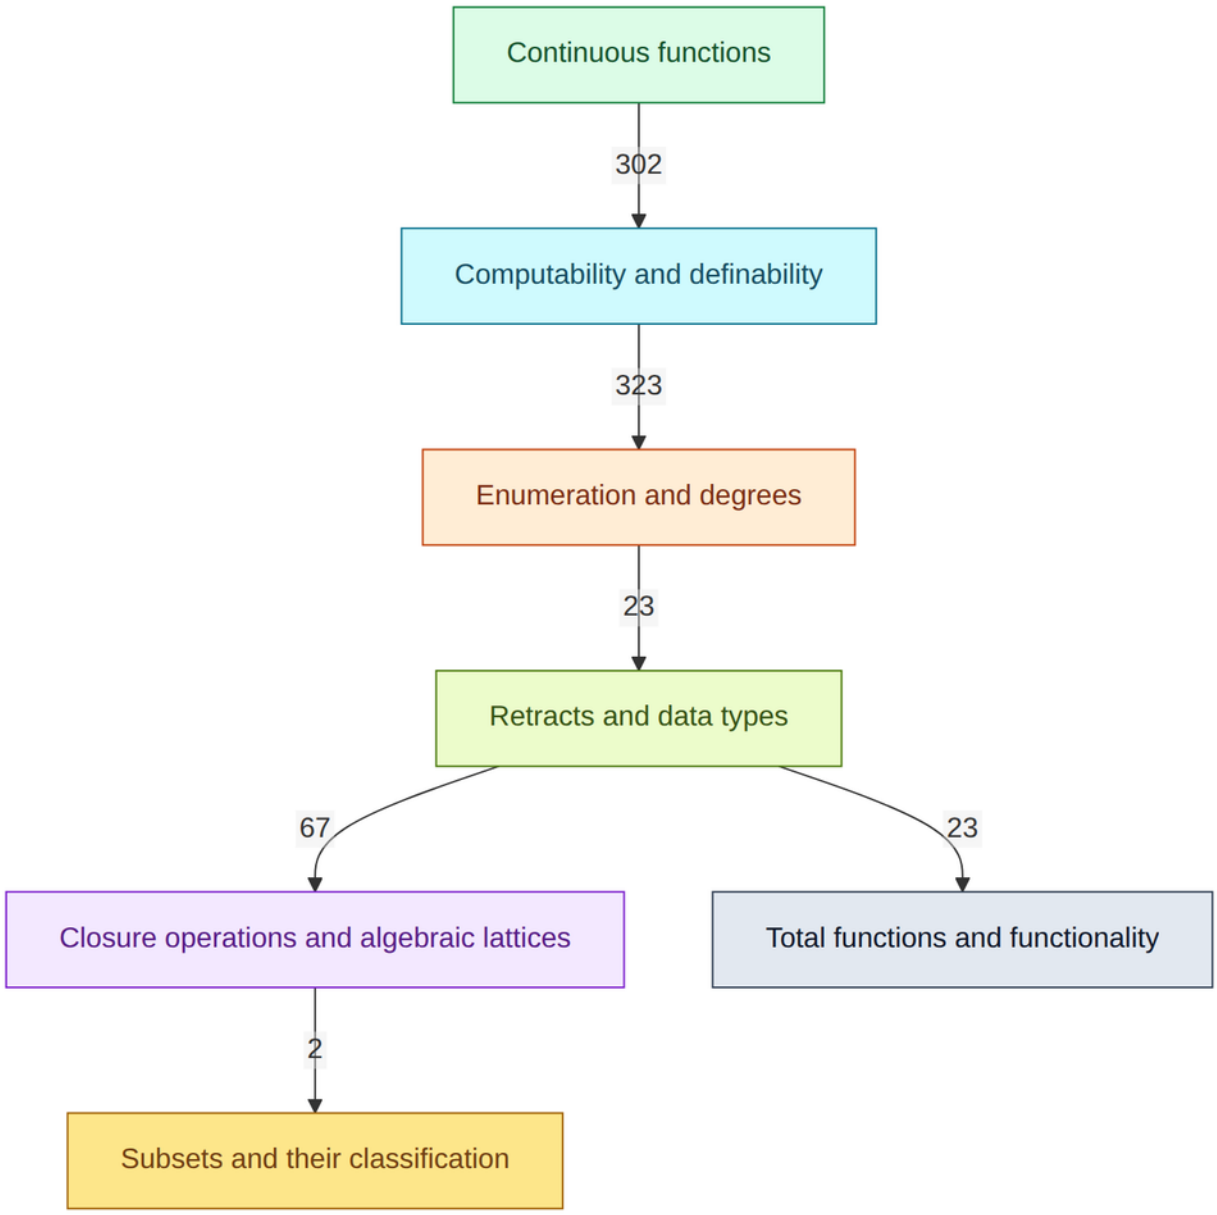

Figure 21: Datatypes as Lattices (1976) ✓.

3.1 Introduction

To the Memory of Christopher Strachey, 1916–1975

Abstract. The meaning of many kinds of expressions in programming languages can be taken as elements of certain spaces of "partial" objects. In this report these spaces are modeled in one universal domain $\mathbf{P}\omega$, the set of all subsets of the integers. This domain renders the connection of this semantic theory with the ordinary theory of number theoretic (especially general recursive) functions clear and straightforward.

Key words. programming language semantics, lattice, continuous lattice, algebraic lattice, computability, retract, combinatory logic, lambda calculus, recursion theorem, enumeration degrees, continuous function, fixed-point theorem

Introduction. Investigations begun in 1969 with Christopher Strachey led to the idea that the denotations of many kinds of expressions in programming languages could be taken as elements of certain kinds of spaces of "partial" objects. As these spaces could be treated as function spaces, their structure at first seemed excessively complicated—even impossible. But then the author discovered that there were many more spaces than we had first imagined—even wanted. They could be presented as lattices (or as some prefer, semilattices), and the main technique was to employ topological ideas, in particular the notion of a continuous function. This approach and its applications have been presented in a number of publications, but that part of the foundation concerned with *computability* (in the sense of recursion theory) was never before adequately exposed. The purpose of the present paper is to provide such a foundation and to simplify the whole presentation by a de-emphasis of abstract ideas. An Appendix and the references provide a partial guide to the literature and an indication of connections with other work.

3.1.1 Domain $\mathbf{P}\omega$ ✓

The main innovation in this report is to model everything within one "universal" domain $\mathbf{P}\omega = \{x \mid x \subseteq \omega\}$, the domain of all subsets of the set ω of nonnegative integers. The advantages are many: by the most elementary considerations $\mathbf{P}\omega$ is recognized to be a lattice and a topological space. In fact, $\mathbf{P}\omega$ is a *continuous lattice*, even an *algebraic lattice*, but in the beginning we do not even need to define such an "advanced" concept; we can save these ideas for an *analysis* of what has been done here in a more direct way. Next by taking the set of integers as the basis of the construction, the connection with the ordinary theory of number-theoretic (especially, general recursive) functions can be made clear and straightforward.

Theorem (`topElem.pos`). Some positive numeral belongs to $\top$.

Proof. $1 \in \top$. ■

3.1.2 Multiple-valued integers ✓

The model $\mathbf{P}\omega$ can be intuitively viewed as the domain of *multiple-valued* integers; what is new in the presentation is that functions are not only multiple-valued but also "multiple-argumented". This remark is given a precise sense in § 2 below, but the upshot of the idea is that multiple-valued integers are regarded as objects in themselves—possibly infinite—and as something more than just the collection of single integers contained in them. This combination of the finite with the infinite into a single domain, together with the idea that a continuous function can be reduced to its *graph* (in the end, a set of integers), makes it possible to view an $x \in \mathbf{P}\omega$ at one time as a value, at another as an argument, then as an integer, then as a function, and still later as a functional (or combinator). The "paradox" of self-application (as in $x(x)$) is solved by allowing the *same* x to be used in two *different* ways. This is done in ordinary recursion theory via Gödel numbers (as in $\{e\}(e)$), but the advantage of the present theory is that not only is the function concept the *extensional* one, but it includes *arbitrary* continuous functions and not just the computable ones.

Section 1 introduces the elementary ideas on the topology of $\mathbf{P}\omega$ and the continuous functions including the fixed-point theorem. Section 2 has to do with computability and definability. The language LAMBDA is introduced as an extension of the pure λ-calculus by four arithmetical combinators; in fact, it is indicated in § 3 how the whole system could be based on *one* combinator. What is shown is that computability in $\mathbf{P}\omega$ according to the natural definition (which assumes that we already know what a recursively enumerable set of integers is) is equivalent to LAMBDA-definability. The main tool is, not surprisingly, the first recursion theorem formulated with the aid of the so-called *paradoxical combinator* $\mathbf{Y}$. The plan is hardly original, but the point is to work out what it all means in the model.

Along the way we have to show how to give every λ-term a denotation in $\mathbf{P}\omega$; the resulting principles of λ-calculus that are thereby verified are summarized in Table 1. Of these the first three, (α), (β), and (ξ), are indeed valid in the model; however, rule (η), which is a stronger version of extensionality, *fails* in the $\mathbf{P}\omega$ model. This should not be regarded as a disadvantage since the import of (η) is to suppose every object is a function. A quick construction of these special models is indicated at the end of § 5. Since $\mathbf{P}\omega$ is partially ordered by $\subseteq$, there are also laws involving this relation. Law (ξ^*) is an improvement of (ξ); while (μ) is a form of monotonicity for application.

TABLE 1

Some laws of λ-calculus

(α)	$\lambda x.\tau = \lambda y.\tau[y/x]$
(β)	$(\lambda x.\tau)(y) = \tau[y/x]$
(ξ)	$\lambda x.\tau = \lambda x.\sigma \quad \text{if} \quad \forall x.\, \tau = \sigma$

(η)	$y = \lambda x.y(x)$
(ξ^*)	$\lambda x.\tau \subseteq \lambda x.\sigma \quad$ if $\quad \forall x.\,\tau \subseteq \sigma$
(μ)	$x \subseteq y$ and $u \subseteq v$ imply $u(x) \subseteq v(y)$

Section 3 has to do with enumeration and degrees. Gödel numbers for LAMBDA are defined in a very easy way which takes advantage of the notation of combinators. This leads to the second recursion theorem, and results on incompleteness and undecidability follow along standard lines. *Relative recursiveness* is also very easy to define in the system, and we make the tie-in with *enumeration degrees* which correspond to finitely generated combinatory subalgebras of $\mathbf{P}\omega$. Finally a theorem of Myhill and Shepherdson is interpreted as a most satisfactory completeness property for definability in the system.

Sections 4 and 5 show how a calculus of *retracts* leads to quite simple definitions of a host of useful domains (as lattices). Section 6 investigates the classification of other subsets (*nonlattices*) of $\mathbf{P}\omega$; while § 7 contrasts partial (multiple-valued) functions with total functions, and interprets various theories of functionality. Connections with category theory are mentioned.

What is demonstrated in this work is how the language LAMBDA, together with its interpretation in $\mathbf{P}\omega$, is an extremely convenient vehicle for *definitions* of computable functions on complex structures (all taken as subdomains of $\mathbf{P}\omega$). It is a "high-level" programming language for recursion theory. It is *applied* combinatory logic, which in usefulness goes far beyond anything envisioned in the standard literature. What has been shown is how many interesting predicates can be *expressed* as equations between continuous functions. What is needed next is a development of the *proof theory* of the system along the lines of the work of Milner, which incorporates the author's extension of McCarthy's rule of recursion induction to this high-level language. Then we will have a flexible and practical "mathematical" theory of computation.

3.2 Continuous functions

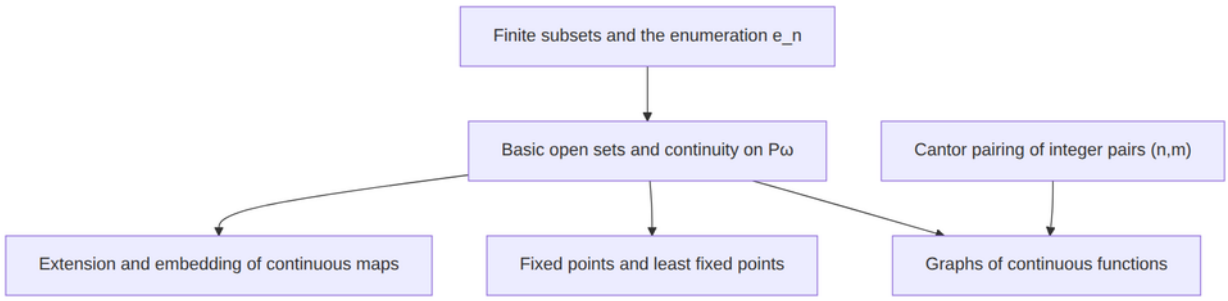

Figure 22: Continuous functions.

3.2.1 Introduction ✓

1. Continuous functions. The domain $\mathbf{P}\omega$ of all subsets of the set ω of nonnegative integers is a complete lattice under the partial ordering $\subseteq$ of set inclusion, as is well known. We use the usual symbols $\cup$, $\cap$, $\bigcup$, $\bigcap$ for the finite and infinite lattice operations of union and intersection. $\mathbf{P}\omega$ is of course also a Boolean algebra; and for complements we write

$$\sim x = \{n \mid n \notin x\}$$

where it is understood that such variables as i, j, k, l, m, n range over *integers in* ω, while u, v, w, x, y, z range over *subsets of* ω.

The domain $\mathbf{P}\omega$ can also be made into a topological space—in many ways. A common method is to match each $x \subseteq \omega$ with the corresponding characteristic function in $\{0,1\}^\omega$, and to take the induced product topology. In this way $\mathbf{P}\omega$ is a totally disconnected compact Hausdorff space homeomorphic to the Cantor "middle-third" set. This is *not* the topology we want; it is a *positive-and-negative* topology which makes the function $\sim x$ continuous. We want a weaker topology: the topology of positive "information", which has the advantage that all continuous functions possess fixed points. (The equation $x = \sim x$ is impossible.) The topology that we *do* want is exactly that appropriate to considering $\mathbf{P}\omega$ to be a continuous lattice. But all this terminology of abstract mathematics is quite unnecessary, since the required definitions can be given in very elementary terms.

For Section 1. If we give the two-point space $\{\bot, \top\}$ the weak T_0-topology with just three open sets: $\varnothing$, $\{\top\}$, $\{\bot, \top\}$, we have what is called the Sierpinski space; and its infinite product $\{\bot, \top\}^\omega$ with the product topology is the same as $\mathbf{P}\omega$. The finite sets $e_n \in \mathbf{P}\omega$ correspond exactly to the usual basic open sets for the product. For those familiar with such notions, this well-known observation makes many of the facts mentioned in this section fairly obvious. From any point of view, Theorem 1.1 and the remarks in the following paragraph are simple exercises.

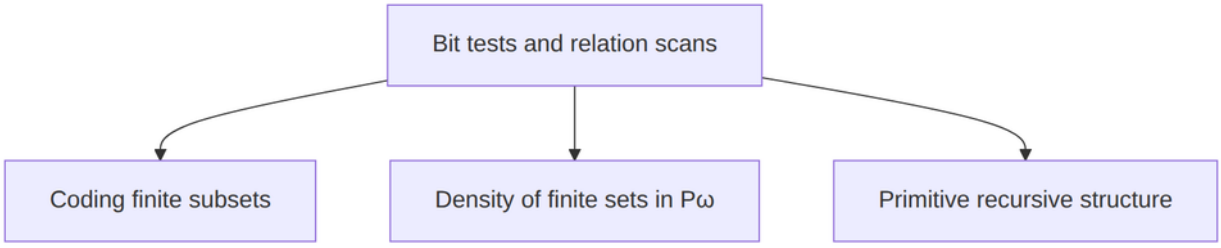

Figure 23: Finite subsets and the enumeration e_n ✓.

Definition of e_n ✓ To make the topology "visible", we introduce a standard enumeration $\{e_n \mid n \in \omega\}$ of all *finite* subsets of ω. Specifically we set

$$e_n = \{k_0, k_1, \cdots, k_{m-1}\},$$

provided that $k_0 < k_1 < \cdots < k_{m-1}$ and $n = \sum_{i<m} 2^{k_i}$. Thus n is the code number for e_n, and the elements of e_n are the exponents in the binary expansion of the integer n.

Definition. For $n \in \omega$, the finite set $e_n \in \mathbf{P}\omega$ is

$$e_n = \{k \in \omega \mid n.\mathrm{testBit}(k)\}.$$

Equivalently, $k \in e_n$ iff the binary expansion of n has a 1 in bit k.

Lemma (`e.mem`). For all $n, k \in \omega$, $k \in e_n \leftrightarrow n.\mathrm{testBit}(k)$.

Proof. This is the definition of membership in $\{k \mid n.\mathrm{testBit}(k)\}$. ■

Theorem (`e.zero`). $e_0 = \emptyset$.

Proof. A natural number has no 1-bits iff it is zero, so membership in e_0 is impossible. Extensionality gives $e_0 = \emptyset$. ■

Theorem (`e.pow2`). For each $k \in \omega$, $e_{2^k} = \{k\}$.

Proof. By `Nat.testBit_two_pow`, 2^k has a 1 in bit i exactly when $i = k$; that is the membership characterization of the singleton $\{k\}$. ■

Theorem (`e.or`). For all $n, m \in \omega$, $e_{n|m} = e_n \cup e_m$, where $|$ is bitwise OR on ω.

Proof. Bit k is set in $n \,|\, m$ iff it is set in n or in m, which is exactly membership in the union $e_n \cup e_m$. ■

Lemma (`e.or_of_subset`). If $e_n \subseteq x$ and $e_m \subseteq x$ for some $x \in \mathbf{P}\omega$, then $e_{n|m} \subseteq x$.

Proof. By `e.or`, $e_{n|m} = e_n \cup e_m$; two set inclusions into x imply the union is contained in x. ■

This is a one-to-one enumeration of finite subsets, where $k \in e_n$ always implies $k < n$,

Lemma (`e.le_two_pow`). For every $k \in \omega$, $k \leq 2^k$.

Proof. Induction on k. For $k = 0$, both sides are 1. For the step $k \to k + 1$, the induction hypothesis gives $k \leq 2^k$, hence $k + 1 \leq 2^k + 1 \leq 2^k + 2^k = 2^{k+1}$. ■

Lemma (`e.two_pow_le_of_testBit`). If $n.\mathrm{testBit}(k)$ is true, then $2^k \leq n$.

Proof. The hypothesis means $(n \gg k) \bmod 2 = 1$, so $n \gg k > 0$. Writing division by 2^k as a right shift, $1 \leq n/2^k$; equivalently $2^k \leq n$. ■

Lemma (`e.lt_two_pow'`). For every $k \in \omega$, $k < 2^k$.

Proof. Induction on k. For $k = 0$, $0 < 1$. For the step, $k + 1 \leq 2^k$ by the induction hypothesis, and $2^k < 2^k + 2^k = 2^{k+1}$ because $2^k > 0$. ■

Lemma (`e.mem_le`). If $k \in e_n$, then $k \leq n$.

Proof. Membership $k \in e_n$ is $n.\mathrm{testBit}(k)$. By `e.two_pow_le_of_testBit`, $2^k \le n$; by `e.le_two_pow`, $k \le 2^k$. Transitivity gives $k \le n$. ■

Theorem (`e.mem_lt`). If $k \in e_n$, then $k < n$.

Proof. By `e.mem_le`, $k \le n$. If $k = n$, then `e.two_pow_le_of_testBit` would give $2^k \le n = k$, while `e.lt_two_pow'` gives $k < 2^k$, a contradiction. So $k \neq n$ and therefore $k < n$. ■

This is the formal content of Scott's clause that $k \in e_n$ always implies $k < n$.

Theorem (`e.finite`). Every set e_n is finite.

Proof. If $k \in e_n$, then `e.mem_le` gives $k \le n$, so $e_n \subseteq \{0, \dots, n\}$. That interval is finite, hence so is e_n. ■

Bit tests and relation scans ✓ The relations Scott treats as primitive recursive are evaluated by scanning binary expansions. This note supplies primitive-recursive bit access and the Boolean procedures that decide membership, inclusion, and union-coding for e_n.

Theorem (`primrec_twoPow`). The function $k \mapsto 2^k$ is primitive recursive.

Proof. Primitive recursion on k with constant 1 and step doubling the accumulator. ■

Theorem (`primrec_testBit`). The function $(n, k) \mapsto n.\mathrm{testBit}(k)$ is primitive recursive.

Proof. Write $\mathrm{testBit}(n, k)$ as parity of $\lfloor n/2^k \rfloor$, using `primrec_twoPow` and division/modulo. ■

Lemma (`not_testBit_of_ge`). If $n \le k$, then $n.\mathrm{testBit}(k) = \mathrm{false}$.

Proof. A true bit would place $k \in e_n$, contradicting `e.mem_lt` with $k \not< n$. ■

Definition (`e.subsetBool`). `e.subsetBool n m` iteratively verifies every 1-bit of n is a 1-bit of m.

Lemma (`e.subsetBool_iff`). `e.subsetBool n m = true` iff $n.\mathrm{testBit}(k) \Rightarrow m.\mathrm{testBit}(k)$ for every k.

Proof. Induction on the scan fuel; bits above n are false by `not_testBit_of_ge`. ■

Theorem (`primrec_e_subsetBool`). `e.subsetBool` is primitive recursive in (n, m).

Proof. A primitive recursive loop on the bit index using `primrec_testBit`. ■

Definition (`e.eqUnionBool`). `e.eqUnionBool n m k` checks $n.\mathrm{testBit}(i) = m.\mathrm{testBit}(i) \vee k.\mathrm{testBit}(i)$ for $i \le n + m + k$.

Theorem (`e.eqUnionBool_iff`). `e.eqUnionBool n m k = true` iff $e_n = e_m \cup e_k$.

Proof. Extensionality on membership, with trivial bits beyond the scan bound. ■

Theorem (`primrec_e_eqUnionBool`). `e.eqUnionBool` is primitive recursive in (n, m, k).

Proof. Same iterator pattern as `e.subsetBool`. ■

Primitive recursive structure ✓ The function $\max(e_n)$ is (primitive) recursive in n, and the relations $k \in e_n$, $e_n \subseteq e_m$, $e_n = e_m \cup e_k$ are all (primitive) recursive in k, m, n.

Theorem (`primrecRel_mem_e`). The relation $(n, k) \mapsto k \in e_n$ is primitive recursive.

Proof. By `e.mem`, membership is $n.\mathrm{testBit}(k)$; apply `primrec_testBit`. ■

Definition (`eMax`). `eMax n` is the greatest $k \le n$ with $n.\mathrm{testBit}(k) = \mathrm{true}$, or 0 if none.

Theorem (`primrec_eMax`). The function `eMax` is primitive recursive.

Proof. `Nat.findGreatest` on the primitive-recursive predicate $n.\mathrm{testBit}(k) = \mathrm{true}$. ■

Theorem (`primrecRel_e_subset`). The relation $(n, m) \mapsto e_n \subseteq e_m$ is primitive recursive.

Proof. By `e.subsetBool_iff`, inclusion equals `e.subsetBool n m = true`; apply `primrec_e_subsetBool`. ■

Theorem (`primrecPred_e_eq_union`). The predicate $(n, m, k) \mapsto e_n = e_m \cup e_k$ is primitive recursive.

Proof. By `e.eqUnionBool_iff`, apply `primrec_e_eqUnionBool`. ■

Theorem (`scott_e_primrec_structure`). Scott's bundled claim: membership in e_n is a primitive recursive relation in (n, k); `eMax` is primitive recursive; inclusion $e_n \subseteq e_m$ is a primitive recursive relation in (n, m); and equality $e_n = e_m \cup e_k$ is a primitive recursive predicate in (n, m, k).

Proof. Conjunction of the four preceding theorems. ■

Coding finite subsets ✓ Scott's definition identifies e_n with the set of bit positions where n has a 1. Every finite subset of ω arises that way; this note gives an explicit constructor and the existence lemmas used later (density, Scott continuity, enumeration).

Definition (`e.codeList`). For a list $k_0 :: \cdots :: k_{m-1} :: []$, `e.codeList` returns $2^{k_0} \mid \cdots \mid 2^{k_{m-1}}$ (and 0 for the empty list).

Theorem (`e.codeList_eq`). For every list `ks` of naturals,

$$e(\texttt{e.codeList}\ ks) = \{k \mid k \in ks\}.$$

Proof. Induction on `ks`. The empty list codes $e_0 = \emptyset$. For `k :: ks`, `e.codeList` ORs in 2^k; by `e.or` and `e.pow2`, membership matches the list membership characterization. ■

Definition (`e.codeFinset`). For a finset `s`, `e.codeFinset s` is `e.codeList` applied to the list of elements of `s` (order as stored in the finset).

Theorem (`e.codeFinset_eq`). For every finset `s` of naturals,

$$e(\texttt{e.codeFinset}\ s) = s$$

as subsets of ω.

Proof. Extensionality using `e.codeList_eq` on the element list. ■

Theorem (`e.exists_code`). Every finset `s` has a code $n \in \omega$ with $e_n = s$ as sets.

Proof. Witness `e.codeFinset s` and `e.codeFinset_eq`. ■

Theorem (`e.exists_code_of_finite`). If $s \in \mathbf{P}\omega$ is finite, then $\exists n,\ e_n = s$.

Proof. Write s as a finset and apply `e.exists_code`. ■

When the exponents k_i are strictly increasing, this agrees with Scott's sum $\sum_{i<m} 2^{k_i}$; duplicate entries in a list would OR the same bit twice, so the finset formulation is the canonical coding for an arbitrary finite set.

Density of finite sets in $\mathbf{P}\omega$ ✓ Topologically speaking the finite sets e_n are *dense* in the space $\mathbf{P}\omega$, for each $x \in \mathbf{P}\omega$ is the "limit" of its finite subsets in the sense that

$$x = \bigcup \{e_n \mid e_n \subseteq x\}.$$

The formalization packages each included finite piece $e_n \subseteq x$ as a subset of $\mathbf{P}\omega$ and unions over all codes n.

Definition (`e.below`). `e.below x n` is $\{k \mid e_n \subseteq x \wedge k \in e_n\}$ (equivalently e_n when $e_n \subseteq x$, and $\emptyset$ otherwise).

Lemma (`e.singleton_eq`). For each $k \in \omega$, the singleton $\{k\}$ equals e_{2^k}.

Proof. This is `e.pow2`, read backwards. ■

Lemma (`e.exists_mem`). If $k \in x$ for $x \in \mathbf{P}\omega$, then there exists n with $e_n \subseteq x$ and $k \in e_n$.

Proof. Witness $n = 2^k$; use `e.singleton_eq` and singleton inclusion. ■

Theorem (`e.union_below_eq`). For every $x \in \mathbf{P}\omega$,

$$\bigcup_n \texttt{e.below}\ x\ n = x.$$

Proof. ($\subseteq$) Each k in the union lies in some $e_n \subseteq x$. ($\supseteq$) For $k \in x$, `e.exists_mem` gives n with $k \in$ `e.below` $x\ n$. ■

This is Scott's density clause before the definition of open sets in $\mathbf{P}\omega$.

3.2.3 Cantor pairing of integer pairs (n, m) ✓

To formulate later definitions we introduce a standard enumeration of all pairs of naturals. The code follows the "little diagonal" ordering Scott describes; the inverse `unpair` is included in Lean for convenience even though the paper does not fix notation for it yet.

Definition (`pair`). The Cantor pairing is

$$\texttt{pair}\ n\ m = \tfrac{1}{2}(n+m)(n+m+1) + m.$$

Definition (`triangle`). Write $T(w) = w(w+1)/2$ for the w-th triangular number: `triangle w`.

Lemma (`pair_eq_triangle`). $\texttt{pair}\ n\ m = T(n+m) + m$.

Proof. Definition of `pair` and `triangle`. ■

Lemma (`triangle_succ`). $T(w+1) = T(w) + (w+1)$.

Proof. Expand $(w+1)(w+2)$ as $w(w+1) + 2(w+1)$ and divide by 2. ■

Lemma (`exists_triangle_bucket`). For every $k \in \omega$ there exists w with $T(w) \le k < T(w{+}1)$.

Proof. The predicate $k < T(w+1)$ holds for $w = k$ because $T(k+1) = T(k) + (k+1)$. Take the least such w by `Nat.find`; minimality gives $T(w) \le k$. ■

Theorem (`exists_pair`). For every $k \in \omega$ there exist n, m with $\texttt{pair}\ n\ m = k$.

Proof. Choose w from `exists_triangle_bucket`. Set $m = k - T(w)$ and $n = w - m$. Then $m \le w$ and $n + m = w$, so `pair_eq_triangle` and $k = T(w) + m$ yield $\texttt{pair}\ n\ m = k$. ■

Definition (`unpair`). `unpair k` is some pair (n, m) with $\texttt{pair}\ n\ m = k$, chosen from `exists_pair`.

Lemma (`pair_le_left`). $n \le \texttt{pair}\ n\ m$.

Proof. Since $n \le n + m$, we have $2n \le (n+m)(n+m+1)$ for $n > 0$, hence $n \le T(n+m)$; the case $n = 0$ is trivial. Then $n \le T(n+m) + m = \texttt{pair}\ n\ m$. ■

Lemma (`pair_lt_left`). $n < \texttt{pair}\ n\ m + 1$.

Proof. From `pair_le_left` and `Nat.lt_succ_self`. ■

Lemma (`pair_le_right`). $m \le \texttt{pair}\ n\ m$.

Proof. $\texttt{pair}\ n\ m = T(n+m) + m \ge m$. ■

Lemma (`pair_lt_right`). $m < \texttt{pair}\ n\ m + 1$.

Proof. From `pair_le_right`. ■

These are Scott's bounds $n \le (n, m)$ and $m \le (n, m)$; strict inequality to $\texttt{pair}\ n\ m + 1$ is the formal counterpart of his remark about equality only at $(0, 0)$ and $(1, 0)$.

Lemma (`pair_unpair`). $\texttt{pair}\ (\texttt{unpair}\ k).1\ (\texttt{unpair}\ k).2 = k$.

Proof. By construction from `exists_pair`. ■

Lemma (`triangle_le_of_le`). If $a \le b$ then $T(a) \le T(b)$.

Proof. Induction on $a \le b$; the step uses `triangle_succ` and monotonicity of addition. ■

Lemma (`triangle_le_pair`). For all n, m,

$$T(n+m) \le \texttt{pair}\ n\ m < T(n+m+1).$$

Proof. The lower bound is $T(n+m) + m \ge T(n+m)$. For the upper bound, `pair_eq_triangle` and `triangle_succ` give $\texttt{pair}\ n\ m = T(n+m) + m < T(n+m) + (n+m+1) = T(n+m+1)$. ■

Lemma (`triangle_lt_of_lt`). If $a < b$ then $T(a) < T(b)$.

Proof. From $a + 1 \le b$, strict inequality $T(a) < T(a+1) = T(a) + (a+1)$ and `triangle_le_of_le`. ■

Theorem (`pair_inj`). If $\texttt{pair}\ n_1\ m_1 = \texttt{pair}\ n_2\ m_2$, then $n_1 = n_2$ and $m_1 = m_2$.

Proof. Compare $w_i = n_i + m_i$ using the window $T(w_i) \le \texttt{pair}\ n_i\ m_i < T(w_i{+}1)$ from `triangle_le_pair`. If $w_1 \neq w_2$, one paired value would lie strictly below the other, contradicting equality. So $w_1 = w_2$; then $T(w) + m_1 = T(w) + m_2$ gives $m_1 = m_2$, and $n_1 + m_1 = n_2 + m_2$ gives $n_1 = n_2$. ■

Theorem (`unpair_pair`). $\texttt{unpair}\ (\texttt{pair}\ n\ m) = (n, m)$.

Proof. `pair_unpair` and injectivity `pair_inj`. ■

Together, `pair` and `unpair` form a bijection $\omega \times \omega \cong \omega$, so this is the one-to-one enumeration Scott asserts (with primitive recursive inverse left informal in the text).

3.2.4 Basic open sets and continuity on $\mathbf{P}\omega$ ✓

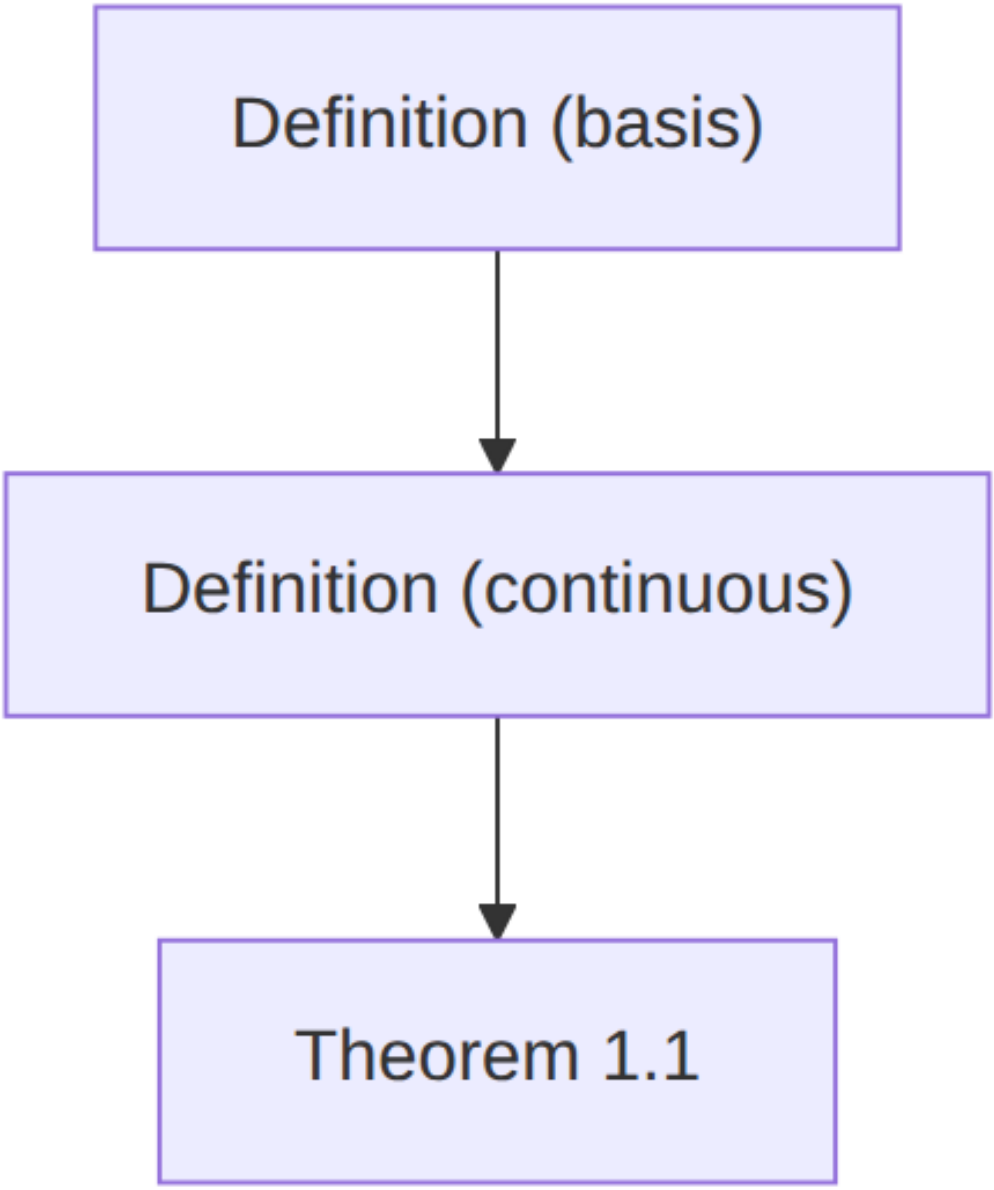

Figure 24: Basic open sets and continuity on $\mathbf{P}\omega$ ✓.

Definition (basis) ✓ **DEFINITION.** A *basis* for the neighborhoods of $\mathbf{P}\omega$ consists of those sets of the form:

$$\{x \in \mathbf{P}\omega \mid e_n \subseteq x\},$$

for a given e_n. An arbitrary *open subset* is then a union of basic neighborhoods.

It is easy to prove that an open subset $U \subseteq \mathbf{P}\omega$ is just a set of "finite character"; that is, a set such that for all $x \in \mathbf{P}\omega$ we have $x \in U$ if and only if some finite subset of x also belongs to U. An alternate approach would define directly what we mean by a continuous function using the idea that such functions must preserve limits.

Definition (`basicNhhd`). For $n \in \omega$, the basic neighborhood is $\mathrm{basicNhhd}\, n = \{x \in \mathbf{P}\omega \mid e_n \subseteq x\}$.

In the `basicNhhd` namespace we define:

Theorem (`inter`). $\mathrm{basicNhhd}\, n \cap \mathrm{basicNhhd}\, m = \mathrm{basicNhhd}\, (n \mid m)$.

Proof. Extensionality: x lies in the intersection iff $e_n \subseteq x$ and $e_m \subseteq x$ iff $e_n \cup e_m \subseteq x$ iff $e_{n|m} \subseteq x$ by `e.or`. ■

Theorem (`zero`). $\mathrm{basicNhhd}\, 0 = \mathbf{P}\omega$.

Proof. Every x satisfies $e_0 \subseteq x$ because $e_0 = \emptyset$ (`e.zero`). ■

Theorem (`mono`). If $e_n \subseteq e_m$, then $\mathrm{basicNhhd}\, m \subseteq \mathrm{basicNhhd}\, n$.

Proof. If $e_m \subseteq x$ and $e_n \subseteq e_m$, then $e_n \subseteq x$. ■

end DomainTheory.DataTypesAsLattices
```

Definition (continuous) ✓ **DEFINITION.** A function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is *continuous* iff for all $x \in \mathbf{P}\omega$ we have:

$$f(x) = \bigcup \{ f(e_n) \mid e_n \subseteq x \}.$$

Again it is an easy exercise to prove that a function is continuous in the sense of this definition iff it is continuous in the usual topological sense (namely: inverse images of open sets are open). For giving proofs it is even more convenient to have the usual ε-δ formulation of continuity.

Definition (`scottPiece, scottUnion`). For $f : \mathbf{P}\omega \to \mathbf{P}\omega$, $x \in \mathbf{P}\omega$, and $n \in \omega$, let $\mathrm{scottPiece}\, f\, x\, n = \{k \mid e_n \subseteq x \wedge k \in f(e_n)\}$ and $\mathrm{scottUnion}\, f\, x = \bigcup_n \mathrm{scottPiece}\, f\, x\, n$. This is exactly Scott's union $\bigcup\{f(e_n) \mid e_n \subseteq x\}$.

Definition (`IsScottContinuous`). The typeclass `IsScottContinuous` on $f : \mathbf{P}\omega \to \mathbf{P}\omega$ packages the field `out`: for every x, $f(x) = \mathrm{scottUnion}\, f\, x$.

In the `IsScottContinuous` namespace:

Theorem (`monotone`). If f is Scott-continuous and $x \subseteq y$ in $\mathbf{P}\omega$, then $f(x) \subseteq f(y)$.

Proof. Take $m \in f(x)$. By `out` and `mem_scottUnion`, choose n with $e_n \subseteq x$ and $m \in f(e_n)$. Then $e_n \subseteq y$, so the same witness shows $m \in f(y)$ via `mem_scottUnion`. ■

Theorem (`determined`). If f and g are Scott-continuous and $f(e_n) = g(e_n)$ for every $n \in \omega$, then $f = g$.

Proof. For each x, `out` rewrites $f(x)$ and $g(x)$ as $\mathrm{scottUnion}\, f\, x$ and $\mathrm{scottUnion}\, g\, x$; extensionality on pieces uses `scottPiece` and the hypothesis on finite values $f(e_n)$, $g(e_n)$. ■

Theorem (`iff_continuous`). For $f : \mathbf{P}\omega \to \mathbf{P}\omega$, f is Scott-continuous iff f is continuous for the Scott topology on $\mathbf{P}\omega$ (generated by the basic opens $\mathrm{memOpen}\, k = \{x \mid k \in x\}$).

Proof. ($\Rightarrow$) By `continuous_generateFrom_iff`, it suffices to show each preimage $f^{-1}(\mathrm{memOpen}\, k)$ is Scott-open. Using `isScottOpen_iff_isOpen`, rewrite membership in that preimage as $k \in \mathrm{scottUnion}\, f\, x$ when $f(x) = \mathrm{scottUnion}\, f\, x$ (`out`), then as an union over indices n with $k \in f(e_n)$ and $e_n \subseteq x$ via `mem_scottUnion`; the converse direction uses `monotone` on the chosen finite witness.

($\Leftarrow$) Fix x and k. If $k \in f(x)$, Scott-openness of $f^{-1}(\mathrm{memOpen}\, k)$ (`isScottOpen_iff_isOpen`, preimage of the open set $\mathrm{memOpen}\, k$ by `isOpen_memOpen`) gives a union of basic neighborhoods $\mathrm{basicNhhd}\, n$ covering x; some $e_n \subseteq x$ still carries $k \in f(e_n)$, hence $k \in \mathrm{scottUnion}\, f\, x$ by `mem_scottUnion`. If $k \in \mathrm{scottUnion}\, f\, x$, pick n with $e_n \subseteq x$ and $k \in f(e_n)$; then $e_n \in f^{-1}(\mathrm{memOpen}\, k)$, and upward closure (`isScottOpen_isUpper`) with $e_n \subseteq x$ puts x in that preimage, so $k \in f(x)$. Thus `out` holds. ■

Theorem (`IsScottOpen.univ`). The whole space $\mathbf{P}\omega$ is Scott-open.

Proof. It is open in the Scott topology. ■

Theorem (`IsScottOpen.empty`). The empty set is Scott-open.

Proof. It is open in the Scott topology. ■

Theorem (`IsScottOpen.union`). The union of two Scott-open sets is Scott-open.

Proof. Openness is preserved by binary unions. ■

Theorem (`IsScottOpen.inter`). The intersection of two Scott-open sets is Scott-open.

Proof. Openness is preserved by binary intersections. ■

Theorem (`IsScottOpen.iUnion`). An arbitrary union of Scott-open sets is Scott-open.

Proof. Openness is preserved by arbitrary unions. ■

Theorem (`IsScottOpen.mem_iff`). If U is Scott-open, then $x \in U$ if and only if some finite $e_n \subseteq x$ already lies in U.

Proof. Unpack the basic-neighbourhood presentation of U, or use upward closure on a finite witness. ■

Theorem (`IsScottContinuous.mem_preimage`). If f is Scott-continuous, then $\{x \mid k \in f(x)\}$ is Scott-open.

Proof. It is the preimage of the subbasic open $\mathrm{memOpen}\, k$. ■

Theorem (`IsScottContinuous.not_subset`). If f is Scott-continuous, then $\{x \mid f(x) \not\subseteq e\}$ is Scott-open.

Proof. Write the set as a union over $k \notin e$ of the preimages $\{x \mid k \in f(x)\}$. ■

Theorem (`IsScottContinuous.subset_preimage`). If f is Scott-continuous and e is finite, then $\{x \mid e \subseteq f(x)\}$ is Scott-open.

Proof. Intersect the finitely many preimages $\{x \mid k \in f(x)\}$ for $k \in e$. ■

Theorem (`IsScottContinuous.ne_eq_open_union_closed`). If f is Scott-continuous and e is finite, then $\{x \mid f(x) \neq e\}$ is the union of $\{x \mid f(x) \not\subseteq e\}$ with the complement of $\{x \mid e \subseteq f(x)\}$, and those two pieces are respectively open and co-open.

Proof. Inequality of sets is failure of either inclusion; apply the two previous facts. ■

Theorem 1.1 ✓ **THEOREM 1.1** (The characterization theorem). A function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is *continuous* iff for all $x \in \mathbf{P}\omega$ and all e_m we have:

$$e_m \subseteq f(x) \quad \text{iff} \quad \exists e_n \subseteq x.\ e_m \subseteq f(e_n).$$

Note that open sets and continuous functions have a *monotonicity property*:
whenever $x \subseteq y$ *and* $x \in U$, *then* $y \in U$; *and*
whenever $x \subseteq y$, *then* $f(x) \subseteq f(y)$.

This gives a precise expression to the "positive" character of our topology. However, note too that openness and continuity mean rather more than just monotonicity. In particular, a continuous function is completely determined by the pairs of integers n, m such that $m \in f(e_n)$, as can be seen from the definition. (Hence, there are only a continuum number of continuous functions, but more than a continuum number of monotonic functions.) This brings us to the definition of the *graph* of a continuous function.

As translated into Lean, we have:

Theorem (`theorem_1_1`). For $f : \mathbf{P}\omega \to \mathbf{P}\omega$, f is Scott-continuous iff for all x and m, $e_m \subseteq f(x)$ iff there exists n with $e_n \subseteq x$ and $e_m \subseteq f(e_n)$.

Proof. The forward direction uses `IsScottContinuous.out` and membership in `scottUnion`/`scottPiece`; the converse rebuilds $f(x)$ as a union of pieces from the ε-δ hypothesis. ■

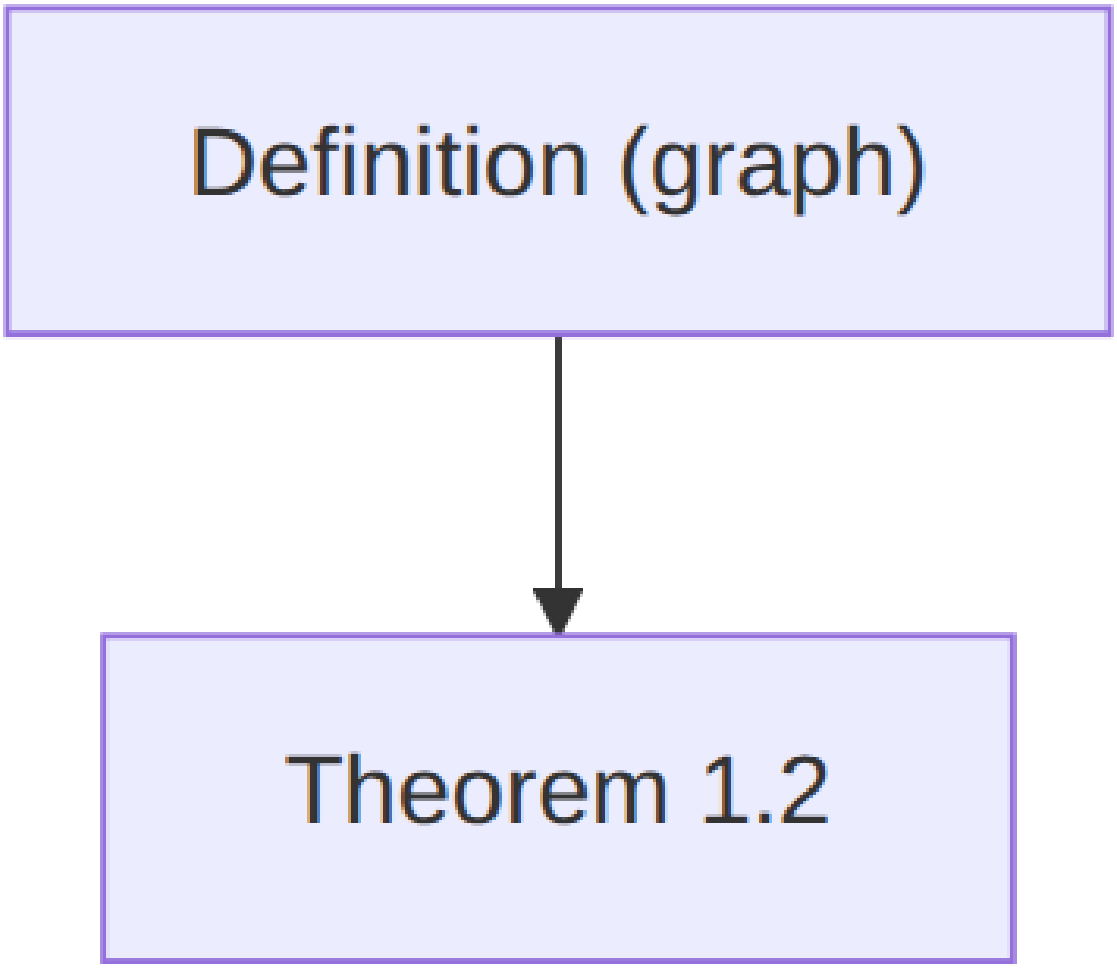

Figure 25: Graphs of continuous functions ✓.

Definition (graph) ✓ **DEFINITION.** The graph of a continuous function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is defined by the equation:

$$\mathbf{graph}(f) = \{(n, m) \mid m \in f(e_n)\};$$

while the function determined by any set $u \subseteq \omega$ is defined by the equation:

$$\mathbf{fun}(u)(x) = \{m \mid \exists e_n \subseteq x.\ (n, m) \in u\}.$$

Theorem 1.2 ✓ **THEOREM 1.2** (The graph theorem). *Every continuous function is uniquely determined by its graph in the sense that:*

(i) $\mathbf{fun}(\mathbf{graph}(f)) = f$.

Conversely, every set of integers determines a continuous function and we have:

(ii) $u \subseteq \mathbf{graph}(\mathbf{fun}(u))$,

where equality holds just in case u satisfies:

(iii) *whenever $(k, m) \in u$ and $e_k \subseteq e_n$, then $(n, m) \in u$.*

Besides functions of one variable we need to consider also functions of several variables. The official definition for one variable given above can be extended simply by saying $f(x, y, \dots)$ is continuous iff it is continuous in each of $x, y, \dots$. Those familiar with the product topology can prove that for our special positive topology on $\mathbf{P}\omega$ this is equivalent to being continuous on the product space (continuous in the variables jointly). Those interested only in elementary proofs can calculate out directly from the definition (with the aid of 1.1) that continuity behaves under combinations by substitution [as in: $f(g(x, y), h(y, x, y))$].

Proof of Theorem 1.2. Equation (i) as a functional equation comes down to

$$\{m \mid \exists e_n \subseteq x.\ m \in f(e_n)\} = f(x),$$

which is just another way of writing the definition of continuity. Thus it is indeed true for all x. Next, inclusion (ii) means that if $(n, m) \in u$, then $\exists e_k \subseteq e_n.\ (k, m) \in u$. Clearly all we need to do is take $k = n$. If we also want the converse inclusion to hold, then what we need is condition (iii).

3.2.6 Fixed points and least fixed points

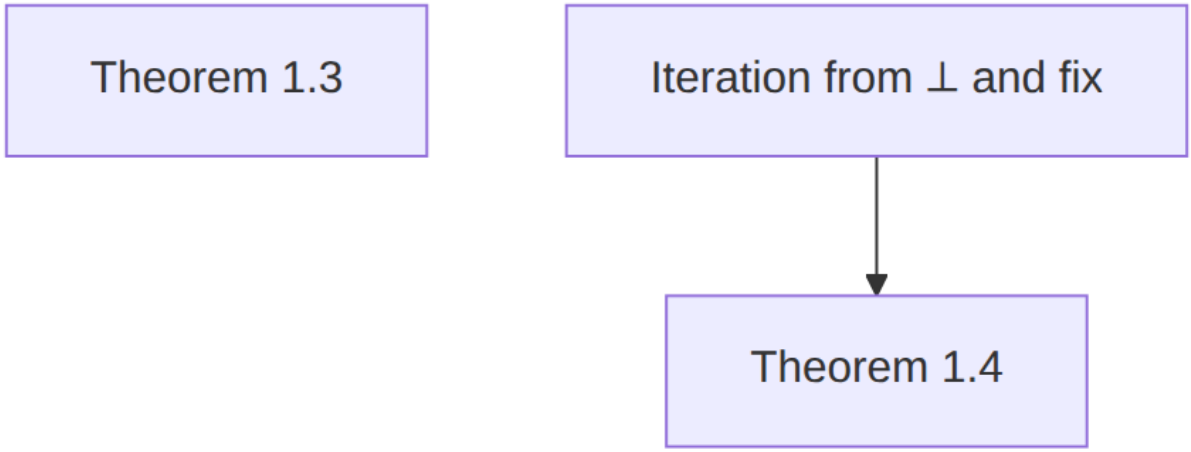

Figure 26: Fixed points and least fixed points.

Theorem 1.3 ✓ **THEOREM 1.3** (The substitution theorem). *Continuous functions of several variables on* $\mathbf{P}\omega$ *are closed under substitution.*

Proof of Theorem 1.3. Substitution is generalized composition of functions of many variables with all possible identifications and permutations of the variables; however, as we are able to define continuity by separating the variables, the argument reduces to a few special cases. The first trick is to take advantage of monotonicity. Thus, suppose $f(x, y)$ is continuous in each of its variables. What can we say of $f(x, x)$, a very special case of substitution? We calculate

$$f(x,x) = \bigcup\{f(e_n, x) \mid e_n \subseteq x\}$$

$$= \bigcup\{f(e_n, e_m) \mid e_n \subseteq x,\ e_m \subseteq x\}.$$

Then if we think of $e_k = e_n \cup e_m$ and realize that $f(e_n, e_m) \subseteq f(e_k, e_k)$, we see that

$$f(x,x) = \bigcup\{f(e_k, e_k) \mid e_k \subseteq x\}.$$

This means that $f(x,x)$ is continuous in x. This same argument works if other variables are present, as in the passage from $f(x,y,z,w)$ to $f(x,x,z,w)$. When an identification of more than two variables is required, as from $f(x,y,z,w)$ to $f(x,x,x,x)$, the principle is just applied several times.

Finally, to show that $f(g(x,y), h(y,x,y))$ is continuous, it is sufficient to show that $f(g(x,y), h(z,u,v))$ is continuous in each of its variables separately. By simply overlooking the remaining variables, this comes down to showing that $f(g(x))$ is continuous if f and g are. But the proof for ordinary composition is very easy with the aid of the characterization theorem (Theorem 1.1).

Formalization. In `theorem_1_3.lean`, namespace `theorem_1_3` holds the special cases; callers use `theorem_1_3.comp`, `theorem_1_3.diag`, etc. The paper's unary composition clause is the top-level theorem `theorem_1_3`.

Lemma (`theorem_1_3.comp`). If f and g are Scott-continuous, then $f \circ g$ is Scott-continuous.

Proof. Membership in $f(g(x))$ is routed through Theorem 1.1 on $g(x)$ and $f(g(x))$, using `mem_scottUnion` and monotonicity. ■

Lemma (`theorem_1_3.diag`). If $F(x,y)$ is continuous in x for each fixed y and in y for each fixed x, then $x \mapsto F(x,x)$ is Scott-continuous; equivalently $F(x,x) = \bigcup\{k \mid \exists n.\, e_n \subseteq x \wedge k \in F(e_n, e_n)\}$.

Proof. Scott's calculation on $f(x,x)$ via $e_n \subseteq x$ and $e_k = e_n \cup e_m$. ■

Lemma (`theorem_1_3.tuple`). Under the same separate-continuity hypothesis on $F(x,y)$, if g and h are Scott-continuous then $x \mapsto F(g(x), h(x))$ is Scott-continuous.

Proof. Apply `theorem_1_3.diag` to $(u,v) \mapsto F(g(u), h(v))$ with `theorem_1_3.comp` on each coordinate. ■

Lemma (`theorem_1_3.nary`). If $F(x,y,z)$ is continuous in each argument separately and g, h, i are Scott-continuous, then $x \mapsto F(g(x), h(x), i(x))$ is Scott-continuous.

Proof. Same pattern: `theorem_1_3.diag` on $(u,v) \mapsto F(g(u), h(u), i(v))$, with `theorem_1_3.tuple` and `theorem_1_3.comp`. ■

Theorem (`theorem_1_3`). If f and g are Scott-continuous, then $x \mapsto f(g(x))$ is Scott-continuous.

Proof. `theorem_1_3.comp`. ■

Corollary (Functionality wrappers). `continuous_on_diag`, `continuous_tuple`, and `continuous_nary` restate the diagonal, binary, and ternary substitution cases for call sites that prefer those names; their proofs invoke `theorem_1_3.diag`, `theorem_1_3.tuple`, and `theorem_1_3.comp` respectively.

Iteration from $\bot$ and fix The other general fact about continuous functions that we shall use constantly concerns fixed points, whose existence can be proved using a well-known method.

Scott's least fixed point is built from iterating f starting at the empty set $\varnothing$ (our $\bot$):

$$\mathbf{fix}(f) = \bigcup\{f^n(\varnothing) \mid n \in \omega\},$$

where $f^0(\varnothing) = \varnothing$ and $f^{n+1}(\varnothing) = f(f^n(\varnothing))$.

Definition (`iterateBot`, `fix`). For $f : \mathbf{P}\omega \to \mathbf{P}\omega$, set $\mathrm{iterateBot}\ f\ 0 = \bot$ and $\mathrm{iterateBot}\ f\ (n+1) = f(\mathrm{iterateBot}\ f\ n)$; then $\mathrm{fix}\ f = \bigcup_n \mathrm{iterateBot}\ f\ n$.

Lemma (`iterateBot_mono`). If f is Scott-continuous, then $\mathrm{iterateBot}\ f\ n \subseteq \mathrm{iterateBot}\ f\ (n+1)$ for every n.

Proof. By induction: the base case is $\bot \subseteq f(\bot)$; the step applies monotonicity of f to the induction hypothesis. ■

Theorem 1.4 **THEOREM 1.4** (The fixed-point theorem). *Every continuous function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ has a least fixed point given by the formula $\mathbf{fix}(f) = \bigcup\{f^n(\varnothing) \mid n \in \omega\}$ (see iteration from $\bot$).*

Actually **fix** is a *functional* with continuity properties of its own. We shall not give the required definitions here because they can be more easily derived from the construction of the model given in the next section.

For those familiar with the abstract theory of topological spaces we give in conclusion two general facts about continuous functions with values in $\mathbf{P}\omega$ which indicate the scope and generality of our method.

Proof of Theorem 1.4. This well-known fact holds for continuous functions on many kinds of chain-complete partial orderings; but $\mathbf{P}\omega$ illustrates the idea well enough. Suppose f had a fixed point $x = f(x)$.

Then since $\varnothing \subseteq x$ and f is monotonic, we see that $f(\varnothing) \subseteq f(x) = x$. But then again, $f(f(\varnothing)) \subseteq f(x) = x$; and so by induction, $f^n(\varnothing) \subseteq x$. This proves that $\mathbf{fix}(f) \subseteq x$; and thus if $\mathbf{fix}(f)$ is a fixed point, it must be the least one. To prove that it is a fixed point, we need a fact that will often be useful:

LEMMA (`chain_lemma`). *If $x_n \subseteq x_{n+1}$ for all n, and if f is continuous, then*

$$f\Big(\bigcup\{x_n \mid n \in \omega\}\Big) = \bigcup\{f(x_n) \mid n \in \omega\}.$$

Proof. By monotonicity, the inclusion holds in one direction. Suppose $e_m \subseteq f(\bigcup\{x_n \mid n \in \omega\})$. Then by Theorem 1.1 we have $e_m \subseteq f(e_k)$ for some $e_k \subseteq \bigcup\{x_n \mid n \in \omega\}$. Because e_k is finite and the sequence is increasing, we can argue that $e_k \subseteq x_n$ for some n. But then $f(e_k) \subseteq f(x_n)$. This shows that $e_m \subseteq \bigcup\{f(x_n) \mid n \in \omega\}$ and proves the inclusion in the other direction. (*Exercise:* Does this property characterize continuous functions?)

Proof of Theorem 1.4 concluded. Noting that $f^n(\varnothing) \subseteq f^{n+1}(\varnothing)$ holds for all n, we can calculate:

$$f(\mathbf{fix}(f)) = \bigcup\{f(f^n(\varnothing)) \mid n \in \omega\} = \bigcup\{f^{n+1}(\varnothing) \mid n \in \omega\}.$$

But this is just $\mathbf{fix}(f)$, since the only term left out is $f^0(\varnothing) = \varnothing$.

Formalization. `theorem_1_4` is Scott's statement; the proof uses `chain_lemma` (via `exists_index_of_finset` and `chain_mono`).

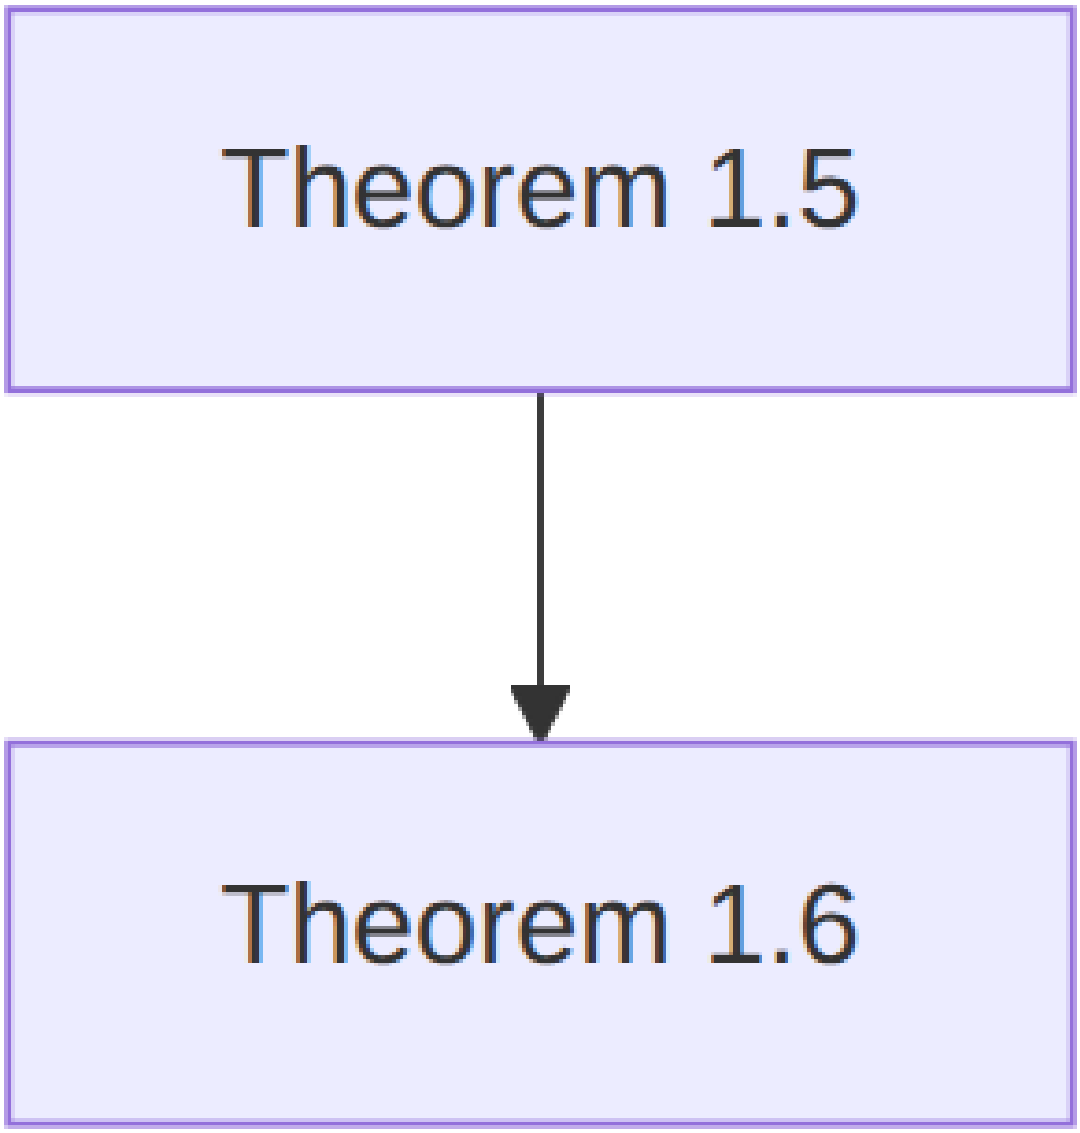

Figure 27: Extension and embedding of continuous maps.

Theorem 1.5 **THEOREM 1.5** (The extension theorem). *Let X and Y be arbitrary topological spaces where $X \subseteq Y$ as a subspace. Then every continuous function $f : X \to \mathbf{P}\omega$ can be extended to a continuous function $\bar{f} : Y \to \mathbf{P}\omega$ defined by the equation:*

$$\bar{f}(y) = \bigcup\{\bigcap\{f(x) \mid x \in X \cap U\} \mid y \in U\},$$

where $y \in Y$, and U ranges over the open subsets of Y.

Proof of Theorem 1.5. The function $\bar{f}$ is clearly well-defined even when $y \in Y$ has a neighborhood U where $X \cap U = \varnothing$: in that case $\bar{f}(y) = \omega$ by convention on the meaning of $\bigcap$ in $\mathbf{P}\omega$. In case $x \in X$, it is obvious that $\bar{f}(x) \subseteq f(x)$. For the opposite inclusion, suppose that $m \in f(x)$. Because f is continuous and $\{z \mid m \in z\}$ is open in $\mathbf{P}\omega$, there is an open subset V of X such that $x' \in V$ always implies that $m \in f(x')$. But X is a subspace of Y, so $V = X \cap U$ for some open subset U of Y. Thus we can see why $m \in \bar{f}(x)$. It remains to show that $\bar{f}$ is itself continuous.

We must show that the inverse image under $\bar{f}$ of every open subset of $\mathbf{P}\omega$ is open in Y. But the open subsets of $\mathbf{P}\omega$ are unions of finite intersections of sets of the form $\{z \mid m \in z\}$. Thus it is enough to show that $\{y \mid m \in \bar{f}(y)\}$ is always open in Y. But this set equals $\bigcup\{U \mid m \in \bigcap\{f(x) \mid x \in X \cap U\}\}$, which being a union of open sets is open. Note that what we have proved is that $\bar{f}$ is continuous no matter what function f is given; however, if f is not continuous, then $\bar{f}$ cannot be an extension of f.

For readers not as familiar with general topology we note that the idea of Theorem 1.5 can be turned into a *definition*. Suppose $X \subseteq \mathbf{P}\omega$ is a subset of $\mathbf{P}\omega$. It becomes a subspace with the relative topology. What are the continuous functions $f : X \to \mathbf{P}\omega$? From Theorem 1.5 we see that a necessary and sufficient condition is that $\bar{f} : \mathbf{P}\omega \to \mathbf{P}\omega$ be an extension of f. Thus for $x \in X$ we can write the equation $f(x) = \bar{f}(x)$ as a biconditional:

$$m \in f(x) \quad \text{iff} \quad \exists e_n \subseteq x \; \forall x' \in X \; [e_n \subseteq x' \text{ implies } m \in f(x')],$$

which is to hold for all $m \in \omega$. This form of the definition of continuity on a subspace is more complicated than the original definition, because in general $e_n \notin X$ and we cannot write $f(e_n)$.

Theorem 1.6 **THEOREM 1.6** (The embedding theorem). *Every T_0-space X with a countable basis $\{U_n \mid n \in \omega\}$ for its topology can be embedded in $\mathbf{P}\omega$ by the continuous function $\varepsilon : X \to \mathbf{P}\omega$ defined by the equation:*

$$\varepsilon(x) = \{n \mid x \in U_n\}.$$

Technically the T_0-hypothesis is what is needed to show that ε is one-to-one. The upshot of these two theorems is that in looking for (reasonable) topological structures we can confine attention to the subspaces of $\mathbf{P}\omega$ and to continuous functions defined on *all* of $\mathbf{P}\omega$. Thus the emphasis on a single space is justified structurally. What we shall see in the remainder of this work is that the use of a single space is also justified practically because the required subspaces and functions can be *defined* in very simple ways by a natural method of equations.

Proof of Theorem 1.6. What T_0 means is that every point of X is uniquely determined by its neighborhoods. Now $\varepsilon(x)$ just tells you the set of indices of the (basic) neighborhoods of x. Thus it is clear that ε is one-to-one. To prove that it is continuous, we need only note:

$$\{x \mid n \in \varepsilon(x)\} = U_n,$$

which is always open. To show that ε is an embedding, we must finally check that the *images* of the open sets U_n are open in $\varepsilon(X)$. This comes down to showing:

$$\varepsilon(U_n) = \varepsilon(X) \cap \{z \mid n \in z\},$$

which is clear.

3.3 Computability and definability

Historical note. The language LAMBDA is Scott's. Plotkin and Rogers already used graphs, application, and conversion; the abstraction operation is what this section supplies.

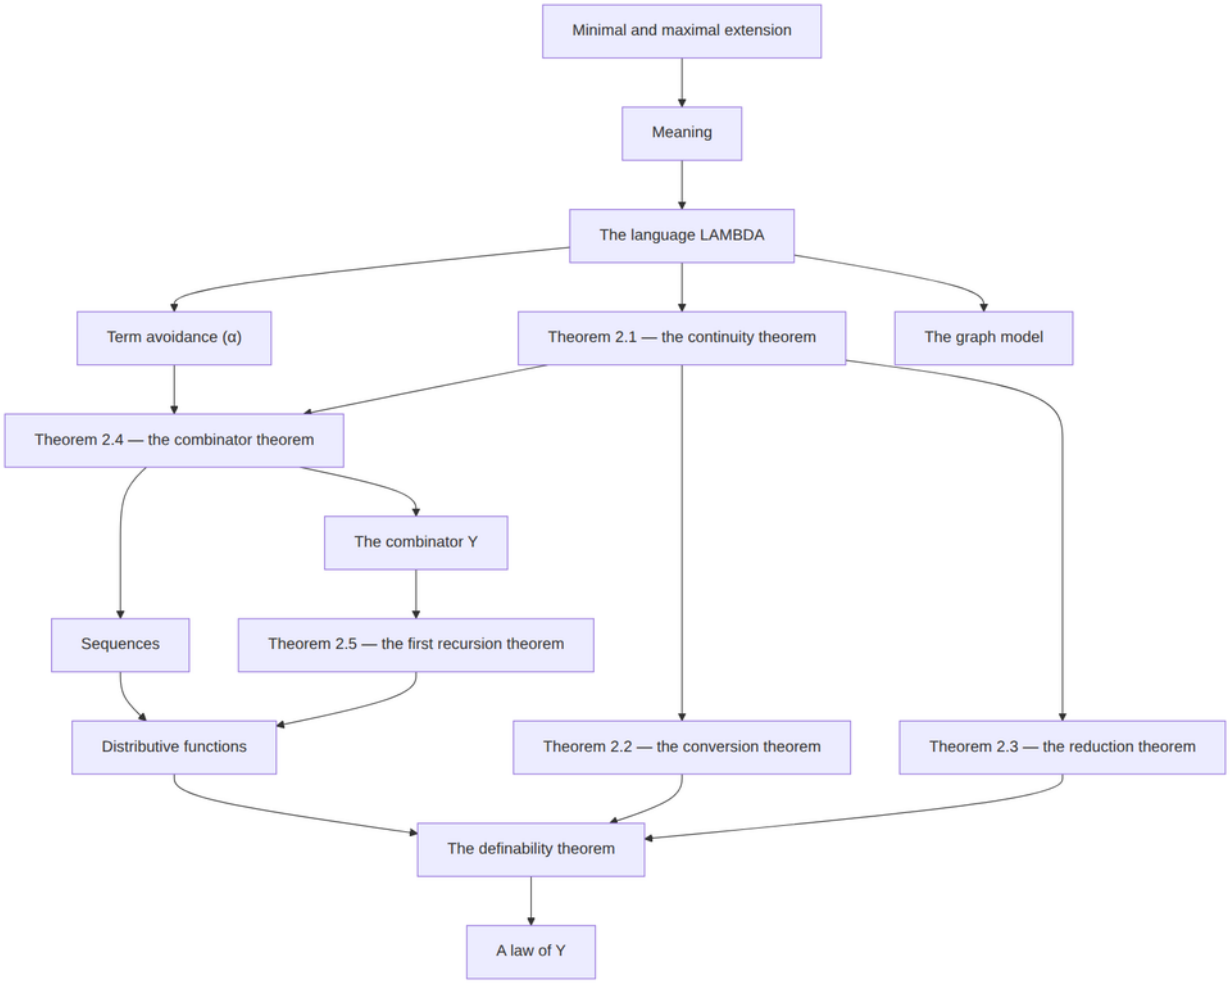

Figure 28: Computability and definability.

3.3.1 Minimal and maximal extension ✓

As a subspace $\omega \subseteq \mathbf{P}\omega$ is discrete. This implies that arbitrary functions $p : \omega \to \omega$ are continuous. Note that $p : \omega \to \mathbf{P}\omega$ as well, because $\omega \subseteq \mathbf{P}\omega$. By Theorem 1.5 we can extend p continuously to $\bar{p} : \mathbf{P}\omega \to \mathbf{P}\omega$. The formula given produces this function:

$$\bar{p}(x) = \begin{cases} \bigcap\{p(n) \mid n \in \omega\} & \text{if } x = \varnothing; \\ p(n) & \text{if } x = n \in \omega; \\ \omega & \text{otherwise.} \end{cases} \tag{2.1}$$

This is a rather abrupt extension of p (the *maximal extension*); a more gradual, continuous extension (the *minimal extension*) is determined by this equation:

$$\hat{p}(x) = \bigcup\{p(n) \mid n \in x\}. \tag{2.2}$$

The same formulae work for *all* multiple-valued functions $p : \omega \to \mathbf{P}\omega$. Functions like $f = \hat{p}$ are exactly characterized as being those continuous functions $f : \mathbf{P}\omega \to \mathbf{P}\omega$ which in addition are *distributive* in the sense of these equations:

$$f(x \cup y) = f(x) \cup f(y) \quad \text{and} \quad f(\varnothing) = \varnothing.$$

Definition (`maxExtend`, `minExtend`). For $p : \omega \to \mathbf{P}\omega$ and $x \in \mathbf{P}\omega$, the maximal extension is $\mathrm{maxExtend}\, p\, x$ (Scott's piecewise $\bar{p}(x)$ in (2.1)), and the minimal extension is $\mathrm{minExtend}\, p\, x = \bigcup\{p(n) \mid n \in x\}$.

Theorem (`eq_2_1_empty`). $\mathrm{maxExtend}\, p\, \bot = \bigcap_n p(n)$.

Proof. On $\bot$, membership in $\mathrm{maxExtend}\, p\, \bot$ is equivalent to $k \in p(n)$ for every n. ■

Theorem (`eq_2_1_singleton`). For $n \in \omega$, $\mathrm{maxExtend}\, p\, (\mathrm{ofNat}\, n) = p(n)$.

Proof. Case-split on the three disjuncts in the definition of $\mathrm{maxExtend}$; the singleton case is the only viable branch. ■

Theorem (`eq_2_1_else`). If $x \neq \bot$ and x is not a singleton $\mathrm{ofNat}\, n$, then $\mathrm{maxExtend}\, p\, x = \top$.

Proof. Every k satisfies the third disjunct in the definition. ■

Theorem (`minExtend.bot`). $\mathrm{minExtend}\, p\, \bot = \bot$.

Theorem (`minExtend.union`). $\mathrm{minExtend}\, p\, (x \cup y) = \mathrm{minExtend}\, p\, x \cup \mathrm{minExtend}\, p\, y$.

Theorem (`minExtend.isScottContinuous`). $\mathrm{minExtend}\, p$ is Scott-continuous for every $p : \omega \to \mathbf{P}\omega$.

Proof. Compare membership in $\mathrm{minExtend}\, p\, x$ with membership in $\mathrm{scottUnion}\, (\mathrm{minExtend}\, p)\, x$ via finite singleton witnesses e_{2^n}. ■

3.3.2 Meaning ✓

The purpose of the first section was to introduce in a simple-minded way the basic notions about the topology of $\mathbf{P}\omega$ and its continuous functions. In this section we wish to present the details of a powerful language for defining *particular* functions—especially computable functions—and initiate the study of the *use* of these functions. This study is then extended in different ways in the following sections.

Before looking at the language, a short discussion of the "meaning" of the elements $x \in \mathbf{P}\omega$ will be helpful from the point of view of motivation. Now in itself $x \in \mathbf{P}\omega$ is a set, but this does not reveal its *meaning*. Actually x has no "fixed" meaning, because it can be *used* in strikingly different ways; we look for meaning here solely in terms of use. Nevertheless it is possible to give some coherent guidelines.

In the first place it is convenient to let the singleton subsets $\{n\} \in \mathbf{P}\omega$ stand for the corresponding integers. In fact, we shall enforce by convention the equation $n = \{n\}$ as a way of simplifying notation. In this way, $\omega \subseteq \mathbf{P}\omega$ as a subset. (Note that our convention conflicts with such set-theoretical equations as $5 = \{0, 1, 2, 3, 4\}$. What we have done is to abandon the usual set-theoretical conventions in favor of a slight redefinition of *set of integers* which produces a more helpful convention for present purposes.) So, if we choose, a singleton "means" a single integer. The next

question is what a "large" set $x \in \mathbf{P}\omega$ could mean. Here is an answer: if we write:

$$x = \{0, 5, 17\} = 0 \cup 5 \cup 17,$$

we are thinking of x as a *multiple integer*. This is especially useful in the case of multiple-valued function where we can write:

$$f(a) = 0 \cup 5 \cup 17.$$

Then "$m \in f(a)$" can be interpreted as "m is one value of f at a." Now $a \in \mathbf{P}\omega$, too, and so it is a multiple integer also. This brings us to an important point.

A multiple integer is (often) *more* than just the (random) collection of its elements. From the definition of continuity, $m \in f(a)$ is equivalent to $m \in f(e_n)$ with $e_n \subseteq a$. We may not be able to reduce this to $m \in f(\{n\})$ with $n \in a$ without additional assumptions on f. Indeed we shall take advantage of the feature of continuous functions whereby the elements of an argument a can join in *cooperation* in determining $f(a)$. Needless to say, continuity implies that the cooperation cannot extend beyond *finite* configurations, and so we can say that a is the union (or limit) of its finite subsets. However, finitary cooperation will be found to be quite a powerful notion.

Where does this interpretation leave the empty set $\varnothing$? When we write "$f(a) = \varnothing$" we can read this as "f has no value at a", or "f is undefined at a". In this case $f(a)$ exists (as a set), but it is not "defined" as an integer. Single- (or singleton-) valued functions are "well-defined", but multiple-valued functions are rather "over-defined".

How does this interpretation fit in with monotonicity? In case $a \subseteq b$ and $m \in f(a)$, then we must have $m \in f(b)$. We can read "$a \subseteq b$" as "b is an *improvement of* a" or "b is *better-defined than* a." The point of monotonicity is that the better we define an argument, the better we define a value. "Better" does not imply "well" (that is, singleton-valuedness), and overdefinedness may well creep in. This is not the fault of the function; it is our fault for not choosing a different function.

The sets $\varnothing$ and ω play special roles. When we consider them as elements of $\mathbf{P}\omega$ we shall employ the notation:

$$\bot = \varnothing \quad \text{and} \quad \top = \omega$$

The element $\bot$ is the most "undefined" integer, and $\top$ is the most "overdefined". All others are in between.

One last general point on meaning: suppose $x \in \mathbf{P}\omega$ and $k \in x$. Then $k = (n, m)$ for suitable (uniquely determined) integers n and m. That is to say, every element of x can be regarded as an ordered pair; thus, x can be used as a relation. Such an operation as

$$(2.3) \quad x; y = \{(n, l) \mid \exists m.\, (n, m) \in x,\, (m, l) \in y\}$$

is then a continuous function of two variables that treats both x and y as relations. On the other hand we could define a quite different continuous function such as

$$(2.4) \quad x + y = \{n + m \mid n \in x,\, m \in y\}$$

which treats both x and y arithmetically. The only reason we shall probably never write $(x + y); x$ again is that the values of this perfectly well-defined continuous function are, for the most part, quite uninteresting. There is, however, no theoretical reason why we cannot use the same set with several different "meanings" in the same formula. Of course if we do so, it is to be expected that we will show the point of doing this in the special case. We turn now to the definition of the general language for defining all such functions.

3.3.3 The language LAMBDA ✓

The syntax and semantics of the language LAMBDA are set out in Table 2. The syntax is indicated on the left, and the meanings of the combinations are shown on the right as subsets of $\mathbf{P}\omega$. This is the basic language and could have been given (less understandably) in terms of combinators (see Theorem 2.4). It

is, however, a very primitive language, and we shall require many definitions before we can see why such functions as in (2.3) and (2.4) are themselves definable.

TABLE 2

The language LAMBDA

$$0 = \{0\}$$

$$x + 1 = \{n + 1 \mid n \in x\}$$

$$x - 1 = \{n \mid n + 1 \in x\}$$

$$z \supset x, y = \{n \in x \mid 0 \in z\} \cup \{m \in y \mid \exists k.\, k + 1 \in z\}$$

$$u(x) = \{m \mid \exists e_n \subseteq x.\, (n, m) \in u\}$$

$$\lambda x.\, \tau = \{(n, m) \mid m \in \tau[e_n/x]\}$$

The definition has been left somewhat informal in hopes that it will be more understandable. In the above, τ is any term of the language. LAMBDA is type-free and allows any combination to be made by substitution into the given functions. There is one primitive constant (0); there are two unary functions $(x + 1,\ x - 1)$; there is one binary function $(u(x))$ and one ternary function $(z \supset x, y)$; finally there is one variable binding operator $(\lambda x.\, \tau)$. The first three equations have obvious sense. In the fourth, $z \supset x, y$ is McCarthy's conditional expression (a test for zero). Next $u(x)$ defines *application* (u is treated as a graph and x as a set), and $\lambda x.\, \tau$ is *functional abstraction* (compare the definition of **fun**). In defining $\lambda x.\, \tau$, we use $\tau[e_n/x]$ as a shorthand for evaluating the term τ when the variable x is given the value e_n.

Note that the functions are all multiple-valued. Thus we have such a result as:

$$(2.5) \quad (6 \cup 10) + 1 = 7 \cup 11.$$

The partial character of subtraction has expression as:

$$(2.6) \quad 0 - 1 = \bot.$$

We shall see how to define $+$ and $-$ in LAMBDA later. The conditional could also have been defined by cases:

$$(2.7) \quad z \supset x, y = \begin{cases} \bot & \text{if } z = \bot; \\ x & \text{if } z = 0; \\ y & \text{if } 0 \notin z \neq \bot; \\ x \cup y & \text{if } 0 \in z \neq 0. \end{cases}$$

We say that a LAMBDA-term τ defines a function of its free variables (at least). Other results depend on this fundamental proposition:

Formalization (`Language.lean`). Below, each Lean name is the library entry; proofs in the file are short unless noted.

Definition (`Comb`). The inductive type of combinator terms: variables x_n, constants 0, suc, pred, cond, K, S, and binary application.

Definition (`Term`). The inductive type of LAMBDA terms: variables x_n; constant 0; unary successor and predecessor; ternary conditional $\mathrm{cond}(z, x, y)$ for $z \supset x, y$; binary application $\mathrm{app}(u, x)$ for $u(x)$; and abstraction $\mathrm{lam}(i, \tau)$ for $\lambda x_i.\, \tau$.

Definition (`ofNat`). For $n \in \omega$, $\mathrm{ofNat}\, n = \{n\} \subseteq \mathbf{P}\omega$.

Theorem (`mem_ofNat`). For all $n, k \in \omega$, $k \in \mathrm{ofNat}\, n \leftrightarrow k = n$.

Proof. By definition of singleton membership. ■

Definition (`predSet`). For $x \in \mathbf{P}\omega$, $\mathrm{predSet}(x) = \{k \in \omega \mid k + 1 \in x\}$ (Table 2's $x - 1$ on sets).

Definition (`succSet`). For $x \in \mathbf{P}\omega$, $\mathrm{succSet}(x) = \{k \in \omega \mid \exists n \in x.\, k = n + 1\}$ (Table 2's $x + 1$ on sets).

Theorem (`e_one`). The standard dense singleton e_1 satisfies $e_1 = \{0\}$.

Proof. $e_1 = e(2^0) = \{0\}$ by the definition of e. ■

Definition (`envSet`). For an environment $\rho : \omega \to \mathbf{P}\omega$, a variable index i, and a value $v \in \mathbf{P}\omega$, $\mathrm{envSet}\, \rho\, i\, v$ is the environment that agrees with ρ except at i, where it is v (formally, a single-point update $\rho[i \mapsto v]$).

Theorem (`envSet.comm`). If $i \neq j$, then for all ρ, v, w,

$$\mathrm{envSet}(\mathrm{envSet}\, \rho\, i\, v)\, j\, w = \mathrm{envSet}(\mathrm{envSet}\, \rho\, j\, w)\, i\, v.$$

Proof. Extensionality on indices; the two updates commute when $i \neq j$. ■

Definition (`Kcomb`). $\mathrm{Kcomb} = \mathbf{graph}(\lambda x.\, \mathbf{graph}(\lambda y.\, x))$, the graph of the K combinator.

Definition (`zeroC`). $\mathrm{zeroC} = \mathrm{ofNat}\, 0$, the denotation of the constant 0.

Definition (`predC`). $\mathrm{predC} = \mathbf{graph}(\mathrm{predSet})$, the graph of predecessor on sets.

Definition (`sucC`). $\mathrm{sucC} = \mathbf{graph}(\mathrm{succSet})$, the graph of successor on sets.

Definition (`rename`). For distinct variable indices treated as a rename $i \rightsquigarrow j$, $\mathrm{rename}\, i\, j : \mathrm{Term} \to \mathrm{Term}$ replaces free occurrences of variable i by j and leaves other constructors unchanged; on $\mathrm{lam}(k, \tau)$ the subterm τ is renamed only when $k \neq i$ (so bound variables are not captured).

Theorem (`triangle_eq_zero`). If $\mathrm{triangle}(w) = 0$, then $w = 0$.

Proof. For $w = n + 1$, the triangular number $T(n + 1) = (n + 1)(n + 2)/2$ is positive, contradicting $T(w) = 0$. ■

Theorem (`pair_zero_zero`). $\mathrm{pair}(0, 0) = 0$.

Theorem (`pair_one_zero`). $\mathrm{pair}(1, 0) = 1$.

Theorem (`pair_eq_right`). If $\mathrm{pair}(n, m) = m$, then $n = 0$ and $m = 0$.

Proof. From $\mathrm{pair}(n, m) = m$ and the identity $\mathrm{pair}(n, m) = \mathrm{triangle}(n+m)+m$, deduce $\mathrm{triangle}(n+m) = 0$, hence $n + m = 0$ by `triangle_eq_zero`, and therefore $n = m = 0$. ■

Theorem (`eq_2_5`). Scott's equation (2.5):

$$\mathrm{succSet}(\mathrm{ofNat}\, 6 \cup \mathrm{ofNat}\, 10) = \mathrm{ofNat}\, 7 \cup \mathrm{ofNat}\, 11.$$

Proof. Extensionality on membership; successor on a singleton $\{n\}$ is $\{n + 1\}$, and union distributes over the operation. ■

Theorem (`eq_2_6`). Scott's equation (2.6): $\mathrm{predSet}(\mathrm{ofNat}\, 0) = \bot$.

Proof. No k satisfies $k + 1 \in \{0\}$. ■

Lemma (`exists_least_mem`). If $a \subseteq \omega$ is nonempty, there exists $k \in a$ such that k is minimal in a (every $i < k$ satisfies $i \notin a$).

Proof. Strong induction on the witness $n \in a$: either n is already minimal below n, or some smaller element of a yields a minimal element by the induction hypothesis. ■

Lemma (`exists_least_not_mem`). If $a \subseteq \omega$ is not all of ω (equivalently, some $k \notin a$), there exists $k \notin a$ minimal with that property (every $i < k$ satisfies $i \in a$).

Proof. Dual to `exists_least_mem`, using strong induction on a witness $n \notin a$. ■

Theorem (`ofNat.combinatory`). Every numeral $\mathrm{ofNat}\, n$ is combinatory.

Proof. By induction: 0 is the zero combinator; successors apply the successor combinator. ■

Theorem (`ofNat.zero_nonempty`). The numeral 0 is nonempty.

Proof. $0 \in \{0\}$. ■

Theorem (`ofNat.zero_not_pos`). No positive numeral belongs to 0.

Proof. Membership in $\{0\}$ forces equality with 0. ■

Theorem (`topElem.ne_ofNat_zero`). $\top \neq 0$.

Proof. Otherwise $1 \in 0$. ■

3.3.4 Term avoidance (α) ✓

Table 1 records the basic laws of λ-conversion verified in the $\mathbf{P}\omega$ model. The first is renaming of bound variables:

$$(\alpha) \quad \lambda x.\, \tau = \lambda y.\, \tau[y/x]$$

(in the usual proviso that y is not free in τ).

Proof of Theorem 2.2 (fragment). The verification of (α) is obvious as the 'x' in '$\lambda x.\, \tau$' is a bound variable. (Care should be taken in making the proviso that 'y' is not otherwise free in τ.) The same would of course hold for any other pair of variables. We do not bother very much about alphabetic questions.

In LAMBDA (Table 2), variables are treated informally and substitution $\tau[e_n/x]$ is used in the semantics of $\lambda x.\, \tau$. In the Lean formalization, terms use de Bruijn-style indices x_i (`Term.var i`), and many

closed combinator terms in §3 are built by recursion on `Term`. To match Scott's proviso mechanically—no accidental capture of a reserved index—we use a small library predicate **`Term.Avoids`**.

Formalization (`Avoids.lean`). Each Lean name is the library entry.

Definition (`Term.Avoids`). For a variable index $i \in \omega$ and a term τ, $\tau.\texttt{Avoids}\, i$ means i does not occur free in τ: - on x_j, require $j \neq i$; - on 0, successor, predecessor, conditional, and application, require the property in each subterm; - on $\lambda x_j.\, \sigma$, require $j = i$ (then i is bound and not free) or $\sigma.\texttt{Avoids}\, i$.

This is the inductive "term avoids index i" check used throughout Enumeration and Computability when proving that a synthesized closed term leaves slots such as x_7 or x_8 free for later composition (Gödel codes, combinator algebra, and similar).

3.3.5 Theorem 2.1 — the continuity theorem ✓

THEOREM 2.1 (The continuity theorem). *All LAMBDA definable functions are continuous.*

Proof of Theorem 2.1. If we did not use the λ-notation, then all LAMBDA-definable functions would be obtained by substitution from the first five (cf. Table 2). Since they are all seen to be continuous, the result would then follow by the substitution theorem (Theorem 1.3). Bringing in λ-abstraction means that we have to combine Theorem 1.3 with this fact:

LEMMA. *If $f(x, y, z, \cdots)$ is a continuous function of all its variables, then $\lambda x.\, f(x, y, z, \cdots)$ is a continuous function of the remaining variables.*

Proof. It is enough to consider one extra variable. We compute from the definition of λ in Table 2 as follows:

$$\lambda x.\, f(x,y) = \{(n,m) \mid m \in f(e_n, y)\}$$

$$= \{(n,m) \mid \exists e_k \subseteq y.\, m \in f(e_n, e_k)\}$$

$$= \bigcup \{\{(n,m) \mid m \in f(e_n, e_k)\} \mid e_k \subseteq y\}$$

$$= \bigcup \{\lambda x.\, f(x, e_k) \mid e_k \subseteq y\}.$$

Thus $\lambda x.\, f(x,y)$ is continuous in y.

3.3.6 Theorem 2.2 — the conversion theorem ✓

Once that is proved, we can use Theorem 1.2 to establish:

THEOREM 2.2 (The conversion theorem). *The three basic principles* (α), (β), (ξ) *of* λ*-conversion are all valid in the model.*

Proof of Theorem 2.2. The reason behind this result is the restriction to continuous functions. Theorem 2.1 shows that we cannot violate the restriction by giving definitions in LAMBDA, and the graph theorem (Theorem 1.2) shows that continuous functions correspond perfectly with their graphs.

The verification of (α) of Table 1 is obvious as the 'x' in '$\lambda x.\, \tau$' is a bound variable. (Care should be taken in making the proviso that 'y' is not otherwise free in τ.) The same would of course hold for any other pair of variables. We do not bother very much about alphabetic questions.

The verification of (β) is just a restatement of Theorem 1.2(i). Let τ define a function f (of x). Then by definition $f(x) = \tau$ and $\lambda x.\, \tau = \mathbf{graph}(f)$. Also $\mathbf{fun}(u)(x)$ in the notation of Theorem 1.2 is the same as the binary operation $u(x)$ in the notation of LAMBDA. Thus in Theorem 1.2(i) if we apply both sides to y we get nothing else than (β).

Half of property (ξ) is already implied by (β): the implication from left to right. (Just apply both sides to x.) In the other direction, $\forall x.\, \tau = \sigma$ means that τ and σ define the *same* function of x; thus, the two graphs must be equal.

Remarks on other laws. The failure of (η) simply means that not every set in $\mathbf{P}\omega$ is the graph of a function. Condition (iii) of Theorem 1.2 is equivalent to saying that $u = \lambda x.\, u(x)$, in other words, u is the graph of some function if and only if it is the graph of the function determined by u.

Law (μ) is the monotone property of application (in both variables); therefore, (μ) and (ξ) together imply (ξ^*) from left to right. Suppose that $\forall x.\, \tau \subseteq \sigma$; then clearly:

$$\{(n, m) \mid m \in \tau[e_n/x]\} \subseteq \{(n, m) \mid m \in \sigma[e_n/x]\},$$

which gives (ξ^*) from right to left.

There are, by the way, other laws valid in the model, as explained in the later results.

3.3.7 Theorem 2.3 — the reduction theorem ✓

By "model" here we of course understand the interpretation of the language where the semantics gives terms denotations in $\mathbf{P}\omega$ according to the stated definition. Through this interpretation, more properly speaking, $\mathbf{P}\omega$ becomes a model for the axioms (α), (β), (ξ). Two well-known results of the calculus of λ-conversion allow the reduction of functions of several variables to those of *one*, and the reduction of all the primitives to *combinators* (constants)—all this with the aid of the binary operation of application.

THEOREM 2.3 (The reduction theorem). *Any continuous function of k-variables can be written as*

$$f(x_0, x_1, \cdots, x_{k-1}) = u(x_0)(x_1)\cdots(x_{k-1}),$$

where u is a suitably chosen element of $\mathbf{P}\omega$.

Proof of Theorem 2.3. This is a standard result in combinatory logic. We have only to put:

$$u = \lambda x_0 \lambda x_1 \cdots \lambda x_{n-1}.\, f(x_0, x_1, \cdots, x_{n-1}).$$

That is, we use the iteration of the process of forming the graph of a continuous function. As each step (from the inside out) keeps everything continuous, we are sure that the equation of Theorem 2.3 will hold for iterated application.

3.3.8 Theorem 2.4 — the combinator theorem ✓

THEOREM 2.4 (The combinator theorem). *The LAMBDA-definable func-*
...tions can be generated (from variables) by iterated application with the aid of these six constants:

$$\mathbf{0} = 0$$

$$\mathbf{suc} = \lambda x.\, x + 1$$

$$\mathbf{pred} = \lambda x.\, x - 1$$

$$\mathbf{cond} = \lambda x \lambda y \lambda z.\, z \supset x, y$$

$$\mathbf{K} = \lambda x \lambda y.\, x$$

$$\mathbf{S} = \lambda u \lambda v \lambda x.\, u(x)(v(x))$$

Proof of Theorem 2.4. This can be found in almost any reference on combinatory logic or λ-conversion. The main idea is to eliminate the λ in favor of the combinators. The fact that we have a few other kinds of terms causes no problem if we introduce the corresponding combinators. The method of proof is to show, for any LAMBDA-term τ with free variables among $x_0, x_1, \ldots, x_{n-1}$, that there is a combination γ of combinators such that:

$$\tau = \gamma(x_0)(x_1)\cdots(x_{k-1}).$$

This can be done by induction on the complexity of τ.

3.3.9 The combinator Y ✓

But the result that makes all this model building and combinatory logic mathematically interesting concerns the so-called *paradoxical combinator* defined by the equation:

$$(2.8) \quad \mathbf{Y} = \lambda u.\,(\lambda x.\,u(x(x)))(\lambda x.\,u(x(x))).$$

Language, model, and bridge. Equation (2.8) is stated in **LAMBDA** (syntax: `Term`, interpretation `interp`). The **model** is $\mathbf{P}\omega$ with application `funOf` and graphs `graph`. We separate three roles in `Ycomb.lean`:

- **Language:** `Yterm` is the closed LAMBDA term for (2.8), using variables x_0, x_1 for the binders in Scott's λu and λx.
- **Model:** `Ycomb` is the element of $\mathbf{P}\omega$ obtained by turning (2.8) into a graph: for each u, apply the ω-subcombinator $\omega(u) = \lambda x.\,u(x(x))$ to itself (formalized as `omegaComb`).
- **Bridge:** `Yterm.interp` shows that under the constant environment $\rho \equiv \lambda i.\,\bot$, we have $\mathrm{interp}(\texttt{Yterm})\,\rho = \texttt{Ycomb}$—the syntax of (2.8) denotes the model element.

The lemmas in `namespace Ycomb` are **model** facts about `funOf Ycomb`; `Ycomb.combinatory` links back to **language** via Theorem 2.4 and the bridge.

Formalization (`Ycomb.lean`). Each Lean name is the library entry; proofs in the file are short unless noted.

Definition (`omegaComb`, in `omegaComb.lean`). For $u \in \mathbf{P}\omega$, $\omega(u) = \mathbf{graph}(\lambda x.\,u(x(x))$, so $\mathrm{funOf}(\omega(u))\,x = \mathrm{funOf}\,u\,(\mathrm{funOf}\,x\,x)$ (`omegaComb.app`).

Definition (`Ycomb`, model). $\texttt{Ycomb} = \mathbf{graph}(\lambda u.\,\mathrm{funOf}(\omega(u))(\omega(u)))$—the graph of $u \mapsto (\lambda x.\,u(x(x)))(\lambda x.\,u(x(x)))$ in the model.

Definition (`Yterm`, language). `Yterm` is the `Term` for (2.8): $\lambda x_0.\,(\lambda x_1.\,x_0(x_1(x_1)))(\lambda x_1.\,x_0(x_1(x_1)))$.

Theorem (`Yterm.interp`, bridge). For $\rho(i) = \bot$ for all i,

$$\mathrm{interp}(\texttt{Yterm})\,\rho = \texttt{Ycomb}.$$

Proof. Unfold `interp`, `Yterm`, `Ycomb`, and `omegaComb`; simplify updates in `envSet`. ■

Theorem (`Ycomb.app`, model). For all $u \in \mathbf{P}\omega$,

$$\mathrm{funOf}(\texttt{Ycomb})\, u = \mathrm{funOf}(\omega(u))(\omega(u)).$$

Proof. Unfold `Ycomb` as a graph and apply (β) (`beta`), using Theorem 1.3 to justify continuity of the underlying map (`theorem_1_3`, `diagApp_isScottContinuous`, `omegaComb.isScottContinuous`). ■

Theorem (`Ycomb.combinatory`, model / language). `IsCombinatory Ycomb`.

Proof. By Theorem 2.4, every closed term's interpretation is combinatory (`theorem_2_4.closed` applied to `Yterm`). Rewrite with `Yterm.interp`. ■

Theorem (`Ycomb.unfold`, model). For all $u \in \mathbf{P}\omega$,

$$\mathrm{funOf}(\texttt{Ycomb})\, u = \mathrm{funOf}\, u\, (\mathrm{funOf}(\texttt{Ycomb})\, u).$$

Proof. Chain `Ycomb.app`, the defining equation for $\omega(u)$ at $x = \omega(u)$ (`omegaComb.app`), and `Ycomb.app` again. This is the graph-model form of the usual Y fixed-point law; Theorem 2.5 treats the case when u is itself a graph. ■

3.3.10 Theorem 2.5 — the first recursion theorem ✓

THEOREM 2.5 (The first recursion theorem). *If u is the graph of a continuous function f, then $\mathbf{Y}(u) = \mathbf{fix}(f)$, the least fixed point of f.*

There are two points to note here: the fixed point is LAMBDA-definable if f is; and $\mathbf{Y}$ defines a continuous operator. The word "recursion" is attached to the theorem because fixed points are employed to solve recursion equations. It would not be correct to call the fixed-point theorem (Theorem 1.4) the recursion theorem since it only shows that fixed points exist and not how they are definable in a language. The *second* recursion theorem (in Kleene's terminology) is related, but it involves Gödel numbers as introduced in § 3.

Proof of Theorem 2.5. The well-known calculation shows that we have from (2.8):

$$\mathbf{Y}(u) = (\lambda x.\, u(x(x)))(\lambda x.\, u(x(x))) = u(\mathbf{Y}(u)).$$

Thus $\mathbf{Y}(u)$ is a fixed point of the function $u(x)$. What is needed is the proof to show that it is the least one.

Let $d = \lambda x.\, u(x(x))$ and let a be any other fixed point of $u(x)$. To show, as we must, that $d(d) \subseteq a$, it is enough to show that $e_l \subseteq d$ always implies $e_l(e_l) \subseteq a$; because by continuity we have:

$$d(d) = \bigcup\{e_l(e_l) \mid e_l \subseteq d\}.$$

By way of induction, suppose that this implication holds for all $n < l$. Assume that $e_l \subseteq d$ and that $m \in e_l(e_l)$. We will want to use the induction hypothesis to show that $m \in a$. By the definition of application, there exists an integer n such that $(n, m) \in e_l$ and $e_n \subseteq e_l$. But $n \leq (n, m) < l$, and $e_n \subseteq d$. By the hypothesis, we have $e_n(e_n) \subseteq a$. Note that $(n, m) \in d$ also, and that d is defined by λ-abstraction; thus,

$m \in d(e_n)$ by definition. By monotonicity $u(e_n(e_n)) \subseteq u(a) = a$; therefore $m \in a$. This shows that $e_l(e_l) \subseteq a$, and the inductive proof is complete.

Remark. Note that we did not actually use the fixed-point theorem in the proof, but we did use rather special properties of the pairing (n, m) and the finite sets e_l.

end DomainTheory.DataTypesAsLattices
```

3.3.11 The graph model ✓

From this point on we see no need to distinguish continuous functions from elements of $\mathbf{P}\omega$; a continuous function will be *identified* with its graph. Note that u is a graph iff $u = \lambda x.\, u(x)$, which is equivalent to Theorem 1.2 (iii). For this reason (functions are graphs) we propose the name *Graph Model* for this model of the λ-calculus. (There is more to LAMBDA than just λ, however.)

The identification of functions with graphs entails that the function space of all continuous functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$ is to be identified (one-to-one) with the subspace

$$\mathbf{FUN} = \{u \mid u = \lambda x.\, u(x)\} \subseteq \mathbf{P}\omega.$$

The identification is *topological* in that the subspace topology agree with the product topology on the function space. This is the topology of pointwise convergence and is closely connected with the lattice structure on the function space which is also defined pointwise (that is, argumentwise). In the notation of λ-abstraction we can express this as the extension of the axiom of extensionality called (ξ^*) in Table 1 of the Introduction. The laws in Table 1 are not the only ones valid in the model, however. We may also note such argumentwise distribution

laws as:

$$(2.9) \quad (f \cup g)(x) = f(x) \cup g(x);$$

$$(2.10) \quad (\lambda x.\, \tau) \cup (\lambda x.\, \sigma) = \lambda x.\, (\tau \cup \sigma);$$

$$(2.11) \quad (f \cap g)(x) = f(x) \cap g(x);$$

$$(2.12) \quad (\lambda x.\, \tau) \cap (\lambda x.\, \sigma) = \lambda x.\, (\tau \cap \sigma).$$

In the above f and g must be graphs. It is also true that if $\mathcal{F} \subseteq \mathbf{P}\omega$, then

$$(2.13) \quad \bigcup\{f \mid f \in \mathcal{F}\}(x) = \bigcup\{f(x) \mid f \in \mathcal{F}\},$$

but the same does not hold for $\cap$.

Formalization (`graph_model.lean`). Scott's (2.9)–(2.11) are stated for graphs f, g and application; in Lean we use `graph` for functional abstraction and prove the union/intersection laws (2.10) and (2.12) in

that form, together with (ξ^*) as `xi_star`. Each name below is the library entry; proofs in the file are short unless noted.

Definition (`graph`). For $F : \mathbf{P}\omega \to \mathbf{P}\omega$, $\mathbf{graph}(F) = \{(n, m) \mid m \in F(e_n)\}$ (pairs coded as `pair n m`).

Theorem (`xi_star`, Table 1 (ξ^*)). If $\tau, \sigma : \mathbf{P}\omega \to \mathbf{P}\omega$ and $\forall x.\, \tau(x) \subseteq \sigma(x)$, then $\mathbf{graph}(\tau) \subseteq \mathbf{graph}(\sigma)$.

Proof. If $(n, m) \in \mathbf{graph}(\tau)$, then $m \in \tau(e_n)$; by hypothesis $m \in \sigma(e_n)$, so $(n, m) \in \mathbf{graph}(\sigma)$. ■

Theorem (`eq_2_10`, equation (2.10)). For all $\tau, \sigma : \mathbf{P}\omega \to \mathbf{P}\omega$,

$$\mathbf{graph}(\tau) \cup \mathbf{graph}(\sigma) = \mathbf{graph}(\lambda x.\, \tau(x) \cup \sigma(x)).$$

Proof. Extensionality on pairs: membership in the left union splits according to membership in $\mathbf{graph}(\tau)$ or $\mathbf{graph}(\sigma)$; on the right, $m \in \tau(x) \cup \sigma(x)$ iff $m \in \tau(x)$ or $m \in \sigma(x)$. ■

Theorem (`eq_2_12`, equation (2.12)). For all $\tau, \sigma : \mathbf{P}\omega \to \mathbf{P}\omega$,

$$\mathbf{graph}(\tau) \cap \mathbf{graph}(\sigma) = \mathbf{graph}(\lambda x.\, \tau(x) \cap \sigma(x)).$$

Proof. If (n, m) lies in both graphs, the argument codes n, m must agree (`pair_inj`); then $m \in \tau(e_n) \cap \sigma(e_n)$. Conversely, if m lies in both value sets at the same e_n, the pair belongs to both graphs. ■

(Equations (2.9) and (2.11) are the same distribution for application and values; (2.13) is not in this file.)

3.3.12 Sequences ✓

Next we use the notation $\langle x_0, x_1, \dots, x_{n-1}\rangle$ for the function $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is defined by:

$$p(i) = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases}$$

$$\langle\rangle = \bot \tag{2.19}$$

$$\langle x\rangle = \lambda z.\, z \supset x, \bot \tag{2.20}$$

$$\langle x, y\rangle = \lambda z.\, z \supset x, (z - 1 \supset y, \bot) \tag{2.21}$$

$$\langle x_0, x_1, \dots, x_n\rangle = \lambda z.\, z \supset x_0, \langle x_1, \dots, x_n\rangle(z - 1). \tag{2.22}$$

Obviously we should formalize the subscript notation so that $u_x = u(x)$; then we find:

$$\langle x_0, x_1, \dots, x_n\rangle_i = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases} \tag{2.23}$$

Formalization (`sequences.lean`). *Finite* tuples $\langle x_0, \dots, x_{n-1}\rangle$ are graphs built from McCarthy conditional (`condSet`) and predecessor on arguments; *infinite* sequences are the spread $\lambda x.\ \bigcup\{u(i) \mid i \in x\}$, approximated by bounded unions `seqFunLt` and defined recursively via `seqShift`. Lean names below are the library entries.

Definition (`seqCons`). `seqCons`$(x, xs) = \mathbf{graph}(\lambda z.\, z \supset x,\ xs(\mathit{pred}\, z))$ — the graph of (2.22): head x, tail read from xs off $z - 1$.

Theorem (`seqCons.body`). The body $z \mapsto \mathit{condSet}(z, x, xs(\mathit{pred}\, z))$ is Scott-continuous.

Proof. `theorem_1_3.tuple` from continuity of conditional, identity, `funOf xs`, and `predSet`. ■

Definition (seq2). $\texttt{seq2}(x, y) = \mathbf{graph}(\lambda z.\, z \supset x,\ (\mathit{pred}\, z \supset y,\ \bot))$ — model form of (2.21) for a pair.

Theorem (seq2.app). $\mathrm{funOf}(\texttt{seq2}\, x\, y)\, z = z \supset x,\ (\mathit{pred}\, z \supset y,\ \bot)$.

Proof. (β) via `seq2.body_isScottContinuous`. ■

Theorem (eq_2_22). Same as `seq2.app` for general `seqCons`: $\mathrm{funOf}(\texttt{seqCons}\, x\, xs)\, z = z \supset x,\ \mathrm{funOf}\, xs\, (\mathit{predSet}\, z)$.

Proof. `seqCons.body` and (β). ■

Theorem (eq_2_23_zero, seq2.zero). $\mathrm{funOf}(\texttt{seq2}\, x\, y)\, 0 = x$ (argument $0 = \mathrm{ofNat}\, 0$).

Proof. Unfold `seq2.app`; case split on conditional and predecessor. ■

Theorem (eq_2_23_one, seq2.one). $\mathrm{funOf}(\texttt{seq2}\, x\, y)\, 1 = y$.

Proof. Same. ■

Theorem (eq_2_23_ge). For all n, $\mathrm{funOf}(\texttt{seq2}\, x\, y)\, (n+2) = \bot$ (empty beyond the pair).

Proof. `seq2.app` and arithmetic on `predSet` / `ofNat`. ■

Theorem (seq2.tag_ne). $\texttt{seq2}(\mathrm{ofNat}\, 0, x) \neq \texttt{seq2}(\mathrm{ofNat}\, 1, y)$ (tags 0 and 1 are distinguishable).

Proof. Apply both sides to argument 0; membership in 0 vs 1 contradicts. ■

Definition (seqFun). $\texttt{seqFun}(u, x) = \bigcup\{\mathrm{funOf}\, u\, (\mathrm{ofNat}\, i) \mid i \in x\}$ — the spread in (2.23) without λ-notation.

Definition (seqFunLt). $\texttt{seqFunLt}(u, x, n) = \bigcup\{\mathrm{funOf}\, u\, (\mathrm{ofNat}\, i) \mid i \in x,\ i < n\}$ — the same union restricted to indices $< n$.

Theorem (mem_seqFunLt). $k \in \texttt{seqFunLt}\, u\, x\, n \leftrightarrow \exists i \in x,\ i < n \wedge k \in \mathrm{funOf}\, u\, (\mathrm{ofNat}\, i)$.

Proof. Unfold `seqFunLt` as a double indexed union. ■

Theorem (seqFun.eq_iUnion_lt). $\texttt{seqFun}(u, z) = \bigcup_n \texttt{seqFunLt}(u, z, n)$.

Proof. Extensionality; each index i contributes at stage $i + 1$. ■

Theorem (seqFun.left_isScottContinuous, seqFun.right_isScottContinuous). $u \mapsto \texttt{seqFun}(u, x)$ and $x \mapsto \texttt{seqFun}(u, x)$ are Scott-continuous.

Proof. Directed unions of Scott-continuous applications (`scottUnion`, `mem_scottUnion`, `funOf.isScottContinuous`). ■

Definition (seqShift). $\texttt{seqShift}(u) = \mathbf{graph}(\lambda z.\, \texttt{seqFun}(u, \mathit{succSet}\, z))$ — reindex tail by successor on arguments (shift u_i to u_{i+1}).

Theorem (seqShift.app, seqShift.ofNat). $\mathrm{funOf}(\texttt{seqShift}\, u)\, z = \texttt{seqFun}(u, \mathit{succSet}\, z)$; at numeric i, $\mathrm{funOf}(\texttt{seqShift}\, u)\, (\mathrm{ofNat}\, i) = \mathrm{funOf}\, u\, (\mathrm{ofNat}(i+1))$.

Proof. Graph (β) and unfold `seqFun` / `succSet`. ■

Definition (termShift). $\texttt{termShift}(u) = \mathbf{graph}(\lambda t.\, \mathrm{funOf}\, u\, (\mathit{succSet}\, t))$ — the same index shift on arbitrary arguments (for LAMBDA terms later).

Theorem (termShift.app, termShift.ofNat). As for `seqShift`, with `funOf` in place of `seqFun`.

Proof. `theorem_1_3` and (β). ■

Theorem (seqFunLt.zero). $\texttt{seqFunLt}\, u\, z\, 0 = \bot$.

Proof. No index $i < 0$. ■

Theorem (seqFunLt.succ).

$$z \supset \mathrm{funOf}\, u\, 0,\ \texttt{seqFunLt}(\texttt{seqShift}\, u, \mathit{predSet}\, z, n) = \texttt{seqFunLt}\, u\, z\, (n+1).$$

This is the recursive step Scott uses because $\cup$ is not primitive in LAMBDA.

Proof. Case split on McCarthy conditional; use `seqShift.ofNat` to align indices. ■

Theorem (`seqFunLt.term`). Same identity with `termShift` in place of `seqShift` (term-level shift for definability proofs).

Proof. Parallel to `seqFunLt.succ`. ■

(Equations (2.19)–(2.20) for empty and singleton tuples are $\bot$ and `seqCons`-special cases; the dollar combinator and full LAMBDA term for `seqFun` continue in later notes.)

3.3.13 Distributive functions ✓

Equation 2.23 gives us the method of LAMBDA-defining *finite sequences* (in a quite natural way), and the next step is to consider *infinite sequences*. But these are just the functions $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is arbitrary. What we need then is a condition expressible in the language equivalent to saying $u = \hat{p}$ for some p. This is the same as

$$u = \lambda x.\ \bigcup\{u_i \mid i \in x\}.$$

but the $\cup$- and set-notation is not part of LAMBDA. We are forced into a recursive definition:

$$(2.24) \quad \$ = \mathbf{Y}(\lambda s \lambda u \lambda z.\ z \supset u_0,\ s(\lambda t.\ u_{t+1})(z-1)).$$

This equation generalizes (2.22) and we have:

$$(2.25) \quad \$(u) = \lambda x.\ \bigcup\{u_i \mid i \in x\}.$$

Thus the combinator \$"revalues" an element as a distributive function. This suggests introducing theλ-notation for such functions by the equation:

$$(2.26) \quad \lambda n \in \omega.\ \tau = \$(\lambda z.\ \tau[z/n]).$$

With all these conventions LAMBDA-notation becomes very much like ordinary mathematical notation without too much strain.

Recall (from minimal extension) that a continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is *distributive* when $f(\varnothing) = \varnothing$ and $f(x \cup y) = f(x) \cup f(y)$. The spread $\hat{p}(x) = \bigcup\{p(n) \mid n \in x\}$ is the canonical example. `seqFun` in `sequences.lean` is $\hat{p}$ at fixed u. The combinator \$packages that revaluation, and (2.26) expresses ω-indexedλ-notation in terms of\$.

Formalization (`distributive_functions.lean`). Scott's (2.24)–(2.26) are split into a **model** step (graphs, `dollarStep`, `dollarC`) and a **language** step (`dollarStepTerm`, `termDollarStep`) linked by `interp` and Theorems 2.4–2.5. Each Lean name is the library entry; proofs in the file are short unless noted.

Definition (`dollarStepBody`). For $s, u, z \in \mathbf{P}\omega$,

$$\texttt{dollarStepBody}(s,u,z) = z \supset \text{funOf}\, u\, 0,\ \text{funOf}(\text{funOf}\, s\, (\texttt{seqShift}\, u))(\mathit{predSet}\, z)$$

— the McCarthy conditional form of the body in (2.24) (head u_0, tail from shifted index family at $z-1$).

Theorem (`dollarStepBody.isScottContinuous_s, ..._u, ..._z`). Each of $s \mapsto \texttt{dollarStepBody}(s,u,z)$, $u \mapsto \texttt{dollarStepBody}(s,u,z)$, and $z \mapsto \texttt{dollarStepBody}(s,u,z)$ is Scott-continuous.

Proof. `theorem_1_3` / `theorem_1_3.tuple` from continuity of `condSet`, `funOf`, `seqShift`, and `predSet`. ■

Definition (`dollarStep`). $\texttt{dollarStep}(s) = \mathbf{graph}(\lambda u.\, \mathbf{graph}(\lambda z.\, \texttt{dollarStepBody}(s,u,z)))$ — the graph of Scott's inner $\lambda u\, \lambda z$ in (2.24) at step parameter s.

Theorem (`dollarStep.isScottContinuous`). `IsScottContinuous dollarStep`.

Proof. `graph_const_isScottContinuous` and the body continuity lemmas. ■

Theorem (`dollarStep.app`, `dollarStep.app2`). $\mathrm{funOf}(\texttt{dollarStep}\, s)\, u = \mathbf{graph}(\lambda z.\, \texttt{dollarStepBod}$ and $\mathrm{funOf}(\mathrm{funOf}(\texttt{dollarStep}\, s)\, u)\, z = \texttt{dollarStepBody}(s,u,z)$.

Proof. (β) on nested graphs. ■

Theorem (`dollarStep.iterate`). For all n, u, z, $\mathrm{funOf}(\mathrm{funOf}(\mathrm{iterateBot}\, \texttt{dollarStep}\, n)\, u)\, z = \texttt{seqFunLt}\, u\, z\, n$.

Proof. Induction on n; base is $\bot$; step uses `dollarStep.app2`, unfold `dollarStepBody`, and `seqFunLt.succ` from `sequences.lean`. ■

Theorem (`dollarStep.fix_app`). $\mathrm{funOf}(\mathrm{funOf}(\mathrm{fix}\, \texttt{dollarStep})\, u)\, z = \texttt{seqFun}\, u\, z$.

Proof. Unfold `fix` as a directed union of iterates; identify with `seqFun.eq_iUnion_lt`. ■

Definition (`termDollarStepBody`, `termDollarStep`). Same as `dollarStepBody` / `dollarStep`, but `termShift` replaces `seqShift` (for interpreting LAMBDA terms that mention u_{t+1}).

Theorem (`termDollarStep.isScottContinuous`, `termDollarStep.app`, `termDollarStep.app2`, `termDollarStep.iterate`, `termDollarStep.fix_app`). Parallel to the `dollarStep` namespace; `iterate` uses `seqFunLt.term`.

Definition (`dollarStepTerm`). Closed `Term` for (2.24):

$$\mathbf{Y}(\lambda s\, \lambda u\, \lambda z.\, z \supset u_0,\ s(\lambda t.\, u_{t+1})(z-1))$$

in de Bruijn indices (`Language` / McCarthy conditional).

Theorem (`dollarStepTerm.interp`). With $\rho(i) = \bot$ for all i,

$$\mathrm{interp}(\texttt{dollarStepTerm})\, \rho = \mathbf{graph}(\texttt{termDollarStep}).$$

Proof. Unfold `interp`, `termDollarStep`, `termShift`, and `condSet`; reflexivity. ■

Definition (`dollarC`, combinator \$).

$$\texttt{dollarC} = \mathbf{graph}(\lambda u.\, \mathbf{graph}(\lambda x.\, \texttt{seqFun}\, u\, x)).$$

Scott's (2.25) is $\$(u) = \lambda x.\, \texttt{seqFun}(u,x)$ in graph form.

Theorem (`dollarC.app`, equation (2.25)). For all $u, x \in \mathbf{P}\omega$,

$$\mathrm{funOf}(\mathrm{funOf}\, \texttt{dollarC}\, u)\, x = \texttt{seqFun}\, u\, x.$$

Proof. `dollarC.app` and (β) using `seqFun.right_isScottContinuous`. ■

Theorem (`dollarC.eq_fix_termDollarStep`). $\texttt{dollarC} = \mathrm{fix}\, \texttt{termDollarStep}$.

Proof. Fixed-point law (Theorem 1.4); show each body value equals `seqFun` on the fixpoint, then re-graph. ■

Theorem (`dollarC.combinatory`). `IsCombinatory dollarC`.

Proof. `funOf Ycomb (interp dollarStepTerm ...) = dollarC` via `dollarStepTerm.interp`, Theorem 2.5, and `eq_fix_termDollarStep`; combine `Ycomb.combinatory` with Theorem 2.4 on the closed term. ■

Theorem (`eq_2_24`, spread recursion). For all $u, x \in \mathbf{P}\omega$,

$$\texttt{seqFun}\, u\, x = x \supset \text{funOf}\, u\, 0,\ \texttt{seqFun}(\texttt{seqShift}\, u)(\mathit{predSet}\, x).$$

This is the set-theoretic recursion underlying (2.24), before introducing \$.

Proof. Extensionality on members; split indices $i \in x$ into $i = 0$ vs $i = j + 1$; rewrite with `seqShift.app` and `ofNat`. ■

Theorem (`eq_2_24.Y`). $\texttt{dollarC} = \text{fix}\,\texttt{dollarStep}$.

Proof. Same pattern as `dollarC.eq_fix_termDollarStep`, using `dollarStep.fix_app`. ■

Theorem (`eq_2_24.Ycomb`, equation (2.24) as Y).

$$\text{funOf}\ \texttt{Ycomb}\ (\mathbf{graph}\ \texttt{dollarStep}) = \texttt{dollarC}.$$

Proof. Theorem 2.5 on `dollarStep.isScottContinuous` and `eq_2_24.Y`. ■

Theorem (`eq_2_25`). Identical to `dollarC.app` (second form of (2.25)).

Definition (`lamOmega`, equation (2.26)). For $\tau : \omega \to \mathbf{P}\omega$ (written $\tau[n]$ for $\tau(n)$),

$$\texttt{lamOmega}\,\tau = \text{funOf}\,\texttt{dollarC}\left(\mathbf{graph}\left(\lambda z.\ \bigcup\{\tau(n) \mid n \in z\}\right)\right).$$

This is Scott's $\lambda n \in \omega.\, \tau$ as \$applied to the graph of the family$z \mapsto \bigcup\{\tau(n) \mid n \in z\}$(formally:\$$(\lambda z.\, \tau[z/n])$ once $[z/n]$ is the term substitution convention).

(Primitive recursion as a distributive function — (2.27) — is in `eq_2_27.lean` / the primitive recursion note.)

`distributive_functions.lean`

3.3.14 The definability theorem ✓

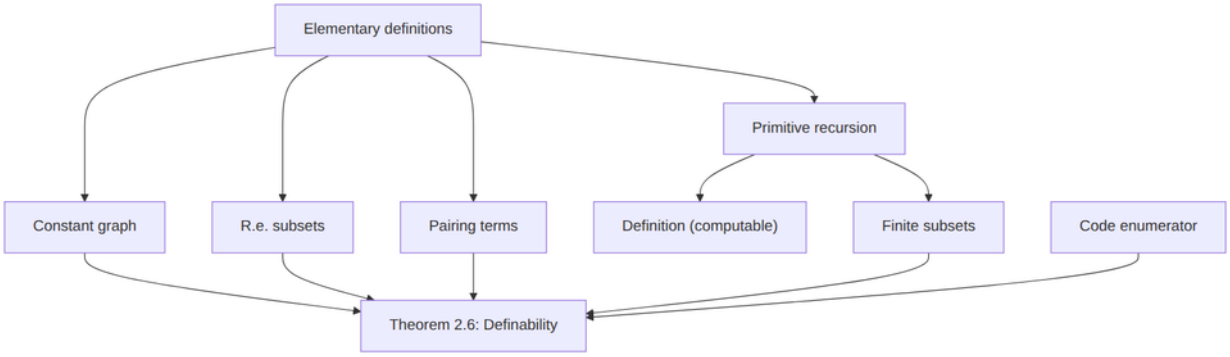

Figure 29: The definability theorem ✓.

Elementary definitions ✓ We state now a sequence of minor results which show why some simple functions and constants are LAMBDA-definable.

$$(2.14) \quad \bot = (\lambda x.\, x(x))(\lambda x.\, x(x));$$

$$(2.15) \quad x \cup y = (\lambda z.\, 0) \supset x, y; \quad \text{(Hint: } 0, 1 \in \lambda z.\, 0)$$

$$(2.16) \quad \top = \mathbf{Y}(\lambda x.\, 0 \cup (x+1));$$

$$(2.17) \quad x \cap y = \mathbf{Y}(\lambda f \lambda x \lambda y.\, x \supset (y \supset 0, \bot), f(x-1)(y-1)+1)(x)(y).$$

The elements $\bot$ and $\top$ are graphs, by the way, and we can characterize them as the only fixed points of the combinator $\mathbf{K}$:

$$(2.18)\quad a = \lambda x.\, a \quad \text{iff} \quad a = \bot \quad \text{or} \quad a = \top.$$

Formalization. Scott's (2.14)–(2.18) are separate library entries; this note's `@import` is `eq_2_18.lean`, which proves (2.18) and also holds the nested `pack4` pairing used later in §2.6. Each name below is the Lean theorem or definition; proofs live in the cited module unless noted.

Theorem (`eq_2_14`, equation (2.14)).

$$\mathrm{funOf}(\omega(\mathrm{id}))(\omega(\mathrm{id})) = \bot,$$

where $\omega(u) = \lambda x.\, u(x(x))$ is `omegaComb` and the left side is Scott's $(\lambda x.\, x(x))(\lambda x.\, x(x))$ as graphs.

Proof. Identify the ω-subcombinator with `graph (fun x => funOf x x)`; apply `omega_first_recursion` so every finite iterate is $\bot$. ■

(Module `eq_2_14.lean`.)

Theorem (`eq_2_15`, equation (2.15)). For all $x, y \in \mathbf{P}\omega$,

$$\mathrm{condSet}(\lambda z.\, 0,\, x,\, y) = x \cup y,$$

with $\lambda z.\, 0$ formalized as `graph (fun _ => ofNat 0)` and $0, 1 \in \lambda z.\, 0$ from membership in that constant graph.

Proof. Case-split on the McCarthy conditional using $0, 1 \in \mathrm{graph}(\lambda z.\, 0)$. ■

(Module `eq_2_15.lean`.)

Theorem (`eq_2_16`, equation (2.16)). $\mathrm{fix}(\texttt{topRec}) = \top$, where `topRec` is the step $x \mapsto 0 \cup (x+1)$ underlying $\mathbf{Y}(\lambda x.\, 0 \cup (x+1))$.

Proof. $\top$ is universal; for membership in $\mathrm{fix}(\texttt{topRec})$, use that iterate $n+1$ already contains n. ■

(Module `eq_2_16.lean`.)

Theorem (`eq_2_17`, equation (2.17)). For all $x, y \in \mathbf{P}\omega$,

$$\mathrm{funOf}(\mathrm{funOf}(\texttt{interC})\, x)\, y = x \cap y,$$

with `interC` the graph of Scott's Y-based intersection step.

Proof. Strong induction on the argument n; unfold `interC.app` and the conditional branches matching (2.17). ■

Theorem (`eq_2_17.step`). The same intersection as a McCarthy recursion:

$$x \cap y = x \supset (y \supset 0,\, \bot),\ f(x-1)(y-1) + 1$$

at the level of `condSet` / `predSet` / `succSet` (the body of (2.17) before abstracting f).

Proof. Extensionality; parallel case analysis to `eq_2_17`. ■

(Module `eq_2_17.lean`.)

Theorem (`eq_2_18.bot`, `eq_2_18.top`). $\bot = \lambda x.\, \bot$ and $\top = \lambda x.\, \top$ as graphs: `botElem = graph (fun _ => botElem)` and `topElem = graph (fun _ => topElem)`.

Proof. For $\bot$, no pair lies in the empty set; for $\top$, every coded pair's value lies in $\mathbf{P}\omega$. ■

Theorem (`eq_2_18`, equation (2.18)). For $a \in \mathbf{P}\omega$,

$$a = \mathbf{graph}(\lambda x.\, a) \leftrightarrow a = \bot \vee a = \top.$$

So the only **K**-fixed graphs are $\bot$ and $\top$.

Proof. If a is a constant graph and $a \neq \top$, least excluded index forces $0 \notin a$; if $a \neq \bot$, least included index yields $0 \in a$ and contradiction. Conversely use `eq_2_18.bot` / `eq_2_18.top`. ■

(Module `eq_2_18.lean` — owner of this note.)

Definition (`pack4`, `pack4.proj1`–`proj4`). Nested `Nat.pair` coding of four naturals and its unpairing projections (not numbered in Scott's (2.14)–(2.18); bundled in `eq_2_18.lean` for §2.6 computability proofs).

`eq_2_18.lean`

Primitive recursion ✓ Suppose that f is any continuous function and $a \in \mathbf{P}\omega$. We can define $p : \omega \to \mathbf{P}\omega$ in the ordinary way by primitive recursion where:

$$p(0) = a;$$

$$p(n+1) = f(n)(p(n)).$$

The question is: can we give a LAMBDA-definition for $\hat{p}$ (in terms of f and a as constants, say)? The answer is clear, for we can prove:

$$(2.27) \quad \hat{p} = \mathbf{Y}(\lambda u \lambda n \in \omega.\, n \supset a,\ f(n-1)(u(n-1))).$$

This already shows that a large part of the definitions of recursion theory can be given in this special language. Of course, simultaneous (primitive) recursions can be transcribed into LAMBDA with the aid of the ordered tuples of (2.22), (2.23) above. But we can go further and connect with partial (and general) recursive functions. We state first a definition.

Formalization (`primitive_recursion.lean`). Scott's scheme $p(0) = a, p(n+1) = f(n)(p(n))$ is `primRecVal`; the spread $\hat{p}(x) = \bigcup\{p(n) \mid n \in x\}$ is `primRecHat`; the recursive step in (2.27) is `primRecStep`; **(2.27)** is `eq_2_27` via \$ (`dollarC`). Each name below is in this module.

Definition (`primRecStepTerm`). LAMBDA term for $\lambda u\, \lambda n.\, n \supset a,\ f(n-1)(u(n-1))$ (de Bruijn form with parameters a, f abstracted).

Theorem (`primRecStepTerm.interp`). Interpretation of `primRecStepTerm` matches the body of `primRecStep` at each u, n.

Proof. Four (β) steps and unfold `interp` / `condSet`. ■

Definition (`primRecStep`). $\texttt{primRecStep}(a, f)(u) = \mathbf{graph}(\lambda n.\, n \supset a,\ f(\mathit{predSet}\, n)(u(\mathit{predSet}\, n)))$ — the step function inside Scott's $\mathbf{Y}$ in (2.27).

Theorem (`primRecStep.body_isScottContinuous_n`). For fixed a, f, and u, the map $n \mapsto (n \supset a,\ f(n-1)(u(n-1)))$ is Scott continuous.

Theorem (`primRecStep.graph_of`). The graph of $u \mapsto \texttt{primRecStep}(a, f)(u)$ is the interpretation of `primRecStepTerm` applied to the parameters a and f.

Theorem (`primRecStep.isScottContinuous`). The map $u \mapsto \texttt{primRecStep}(a, f)(u)$ is Scott continuous.

Theorem (`primRecStep.app`). Applying that graph at n returns $n \supset a,\ f(n-1)(u(n-1))$.

Definition (`primRecVal`). $\texttt{primRecVal}(a, f)(0) = a, \texttt{primRecVal}(a, f)(n{+}1) = \mathrm{funOf}(\mathrm{funOf}\, f\, (\mathrm{ofNat}\, n))(\mathrm{p}$ — the numeric schema above.

Theorem (`primRecVal.fix`). $\mathrm{funOf}(\mathrm{fix}(\texttt{primRecStep}\, a\, f))(\mathrm{ofNat}\, n) = \texttt{primRecVal}(a, f)\, n$ for all n.

Proof. Fixed-point law (Theorem 1.4); case $n = 0$ and $n+1$ via `primRecStep.app` and predecessor lemmas. ■

Definition (`primRecHat`). $\texttt{primRecHat}(a, f)(x) = \bigcup\{\texttt{primRecVal}(a, f)(n) \mid n \in x\}$ — formal $\hat{p}$.

Theorem (`primRecHat.zero`, `primRecHat.ofNat`). $\texttt{primRecHat}(a, f)(0) = a$ and $\texttt{primRecHat}(a, f)(n) = \texttt{primRecVal}(a, f)(n)$ on singletons $\mathrm{ofNat}\, n$.

Theorem (`eq_2_27`, equation (2.27)). For all $a, f, x \in \mathbf{P}\omega$,

$$\texttt{primRecHat}(a, f)(x) = \text{funOf}(\text{funOf}\ \texttt{dollarC}\ (\text{fix}(\texttt{primRecStep}\ a\ f)))(x).$$

Proof. Rewrite with `eq_2_25` (spread as \$); index-wise use `primRecVal.fix`. ■

Definition (`precTerm`). A second LAMBDA term for the same scheme, written with an explicit zero value, step function, and predecessor rather than with $\mathbf{Y}$. The combinator `precC` is its interpretation.

Definition (computable) ✓ **DEFINITION.** A continuous function f of k-variables is *computable* iff the relationship

$$m \in f(e_{n_0})(e_{n_1})\cdots(e_{n_{k-1}})$$

is recursively enumerable (r.e.) in the integer variables $m, n_0, n_1, \ldots, n_{k-1}$.

If q is a partial recursive function in the usual sense, then we can regard it as a mapping $q : \omega \to \omega \cup \{\perp\}$, where $q(n) = \perp$ means that q is undefined at n. Saying that q is partial recursive is just to say that $m \in q(n)$ is r.e. as a relation in n and m. It is easy to see that this is in turn equivalent to the recursive enumerability of the relationship $m \in \hat{q}(e_n)$; and so our definition is formally a generalization of the usual one. But it is also intuitively reasonable. To "compute" $y = f(x)$, in the one-variable case, we proceed by enumeration. First we begin the enumeration of all finite subsets $e_n \subseteq x$. For each of these f starts up an enumeration of the set $f(e_n)$; so we sit back and observe which $m \in f(e_n)$ by enumeration. The totality of all such m for all $e_n \subseteq x$ forms in the end the set y.

R.e. subsets ✓ Scott treats the *recursively enumerable* objects as a subcollection $\mathbf{RE} \subseteq \mathbf{P}\omega$: those elements u whose membership is susceptible to enumeration. In ordinary recursion theory a set $A \subseteq \omega$ is r.e. when the relation "$n \in A$" is recursively enumerable. An element $u \in \mathbf{P}\omega$ is itself a set of natural numbers

(integers coding finite or infinite subsets), so the same idea applies: u is r.e. when one can enumerate the instances of membership $n \in u$.

This is exactly the hypothesis in Theorem 2.6 (ii), where the λ-term associated with a continuous function f is required to be an r.e. *set* of codes. The proof that LAMBDA-definable graphs are r.e. and the construction of r.e. sets from primitive recursive functions both live in the $\mathbf{RE}$ fragment of $\mathbf{P}\omega$ closed under application and definability.

Formalization (`IsRE.lean`). Mathlib's `REPred` captures "recursively enumerable as a predicate on $\mathbb{N}$". For $u \in \mathbf{P}\omega$, **`IsRE u`** holds when $\lambda n.\, n \in u$ is of that kind—equivalently, the membership set $\{\, n \in \omega \mid n \in u \,\}$ is r.e. The proof field is packaged as `IsRE.out`; downstream lemmas use `IsRE` for combinators, application, and Theorem 2.6.

Definition (`IsRE`). $u \in \mathbf{P}\omega$ is **r.e.** iff the membership predicate $n \mapsto (n \in u)$ is recursively enumerable (`IsRE u`).

Theorem (`REPred.empty`). The constantly false predicate on ω is recursively enumerable.

Theorem (`REPred.true`). The constantly true predicate, on any primcodable type, is recursively enumerable.

Theorem (`REPred.or`). If p and q are recursively enumerable predicates on the same primcodable type, then so is $a \mapsto p(a) \vee q(a)$.

Finite subsets The basic neighbourhoods $e_n \subseteq \omega$ are the finite sets coded by the bits of n. The lemmas below are the bit-arithmetic used to treat membership and application as r.e. relations.

Theorem (`lt_two_pow_of_high_bits`). If every bit of n in position k or higher is off, then $n < 2^k$.

Theorem (`bits_subset_lt_two_pow`). If $e_n \subseteq e_b$, then $n < 2^{b+1}$.

Theorem (`eSubset_e_iff`). $e_n \subseteq e_b$ if and only if for every position $k < n$, the bit of n at k is off or the bit of b at k is on.

Theorem (`eSubset_funOf_e_iff`). $e_k \subseteq e_a(e_b)$ if and only if for every position $i < k$, the bit of k at i is off or i lies in the application $e_a(e_b)$.

Theorem (`eSubset_iff_stage`). Suppose the code c returns 0 on input k exactly when $k \in x$. Then $e_n \subseteq x$ if and only if there is a stage s such that, for every position $k < n$, the bit of n at k is off or c has halted on k by stage s.

Theorem (`e_subset_ofNat_iff`). $e_{\mathrm{code}} \subseteq \{n\}$ if and only if $\mathrm{code} = 0$ or $\mathrm{code} = 2^n$.

Pairing terms ✓ Integer pairing and its inverse are written as LAMBDA terms in addition, multiplication, subtraction, square root, and the order test. Write $s = \lfloor \sqrt{n} \rfloor$ and $k = n - s^2$. Mathlib's $\mathrm{Nat.unpair}\, n$ is the pair of components recovered from s and k.

Definition (`pairTerm`). With addition, multiplication, and subtraction supplied, this term applied to the numerals n and m denotes the numeral $\mathrm{Nat.pair}\, n\, m$.

Definition (`unpairSqrtTerm`). Square root applied to the input: the term for s.

Definition (`unpairSquareTerm`). The product of that value with itself: the term for s^2.

Definition (`unpairDeltaTerm`). The input minus that square: the term for k.

Definition (`unpairTestTerm`). The comparison of $k + 1$ with s: the term for the test $k < s$.

Definition (`unpairFstTerm`). The conditional on that test which selects s or k. Interpreted with square root, subtraction, multiplication, and $\leq$, it denotes the first component of $\mathrm{Nat.unpair}\, n$.

Definition (`unpairSndTerm`). The conditional on the same test which selects either $k - s$ or s. In the same interpretation it denotes the second component of $\mathrm{Nat.unpair}\, n$.

Theorem 2.6: Definability ✓ **THEOREM 2.6 (The definability theorem).** *For a k-ary continuous function f, the following are equivalent:*

(i) f is computable;

(ii) $\lambda x_0 \lambda x_1 \cdots \lambda x_{k-1}.\, f(x_0)(x_1)\cdots(x_{k-1})$ as a set is r.e.;

(iii) $\lambda x_0 \lambda x_1 \cdots \lambda x_{k-1}.\, f(x_0)(x_1)\cdots(x_{k-1})$ is LAMBDA-definable.

Proof of Theorem 2.6. In case of a function of several variables, we remark:

$$\lambda x_0 \lambda x_1 \cdots \lambda x_{k-1}.\, f(x_0)(x_1)\cdots(x_{k-1})$$

$$= \{(n_0, (n_1, (\cdots, (n_{k-1}, m)\cdots))) \mid m \in f(e_{n_0})(e_{n_1})\cdots(e_{n_{k-1}})\}.$$

This makes the implication from (i) to (ii) obvious. Conversely, if a graph u is r.e., then from the definition of application we have:

$$m \in u(e_{n_0})(e_{n_1})\cdots(e_{n_{k-1}}) \quad \text{iff} \quad (n_0, (n_1, (\cdots, (n_{k-1}, m)\cdots))) \in u,$$

which is r.e. in $m, n_0, n_1, \ldots, n_{k-1}$. Therefore (i) and (ii) are equivalent.

We have already proved that (ii) implies (iii). For the converse we have only to show that all LAMBDA-definable sets are r.e. For this argument we could take advantage of the combinator theorem, (Theorem

2.4). Each of the six combinators are r.e., and there is no problem of showing that if u and x are r.e., then so is $u(x)$; because it is defined in such an elementary way with existential and bounded universal number quantifiers and with membership in u and in x occurring positively. Explicitly we have:

$$m \in u(x) \quad \text{iff} \quad \exists e_n \subseteq x.\, (n,m) \in u$$

$$\text{iff} \quad \exists n \, \forall m < n \, [[m \in e_n \text{ implies } m \in x] \text{ and } (n,m) \in u].$$

As a hint for the proof we may note that the method of (2.27) shows that all primitive recursive functions p have the corresponding $\hat{p}$ LAMBDA-definable. Next we remark that a nonempty r.e. set is the range of a primitive recursive function; but the range of p is $\hat{p}(\top)$, which is clearly LAMBDA-definable. That any LAMBDA-definable set (graph) is r.e. is obvious from the definition of the language itself. More details are given in the Appendix.

We may draw some interesting conclusions from the definability theorem. In the first place, we see that the countable collection $\mathbf{RE} \subseteq \mathbf{P}\omega$ of r.e. sets is closed under application and LAMBDA-definability. Indeed it forms a model for the λ-calculus (axioms (α), (β), and (ξ^*) at least) and it also contains the arithmetical combinators. (Clearly there will be many intermediate submodels.) In the second place, we can see now how very easy it is to interpret λ-calculus in ordinary arithmetical recursion theory by means of quite elementary operations on r.e. sets. Thus the equivalence of λ-definability with partial recursiveness seems not to be all that good a piece of evidence for Church's Thesis. In his 1936 paper (a footnote on p. 346) Church says about λ-definability:

> The fact, however, that two such widely different and (in the opinion of the author) equally natural definitions of effective calculability turn out to be equivalent adds to the strength of the reasons adduced below for believing that they constitute as general a characterization of this notion as is consistent with the usual intuitive understanding of it.

The point never struck the present author as an especially telling one, and the reduction of λ-calculus to r.e. theory shows that the divergence between the theories is not at all wide. Of course it is a pleasant surprise to see how many complicated things can be defined in pure λ-calculus (without arithmetical combinators), but this fact cuts the wrong way as evidence for the thesis (we want stronger theories, not weaker ones). Post systems (or even first-order theories) are much better to mention in this connection, since they are obviously more inclusive in giving enumerations than Turing machines or Herbrand–Gödel recursion equations. But the equivalence proofs are all so easy! What one would like to see is a "natural" definition where the equivalence with r.e. is not just a mechanical exercise involving a few tricks of coding.

Formalization (`theorem_2_6.lean`).

Theorem (`theorem_2_6`). For a Scott continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$, the following are equivalent: f is computable; the graph of f is r.e.; the graph of f is combinatory; the graph of f is LAMBDA-definable. Combinatory and LAMBDA-definable agree for every set, so the last two are equivalent without using continuity of f.

Theorem (`theorem_2_6.fin`). The same four-way equivalence for a Scott continuous function of n variables, with the graph replaced by its curried form `curryFin`.

Theorem (`theorem_2_6.combinatory_zero`). The zero combinator is LAMBDA-definable.

Theorem (`theorem_2_6.lambda_continuous`). The interpretation of any LAMBDA term, with every variable except one held at $\perp$, is Scott continuous in that variable.

Theorem (`theorem_2_6.ofNat_isRE`). If the numeral for n is combinatory, then it is r.e.

3.3.15 A law of Y ✓

In the course of the development in this section we have stated many equations which are not found in Table 1, and which involve new combinators. In conclusion we would like to mention an equation about $\mathbf{Y}$ which holds in the model, which can be stated in pure λ-calculus, and which cannot be proved by ordinary reduction (though we shall not try to justify this last statement here). In order to shorten the calculations, we note from definition (2.8) that $\mathbf{Y}(u) = \mathbf{Y}(\lambda y.\, u(y))$; so by Theorem 2.5 this also equals $u(\mathbf{Y}(u))$.

$$(2.28) \quad \mathbf{Y}(\lambda f \lambda x.\, g(x)(f(x))) = \lambda x.\, \mathbf{Y}(g(x)).$$

Call the left side f' and the right f''. Now $f'' = \lambda x.\, g(x)(\mathbf{Y}(g(x))) = \lambda x.\, g(x)(f''(x))$, thus $f' \subseteq f''$, because f' is a least fixed point. On the other hand $f' = \lambda x.\, g(x)(f'(x))$, so $f'(x) = g(x)(f'(x))$. Thus $f''(x) \subseteq f'(x)$, because $f''(x)$ is a least fixed point. As this holds for all x, we see that $f'' \subseteq f'$; and so they are equal. There must be many other such equations.

3.4 Enumeration and degrees

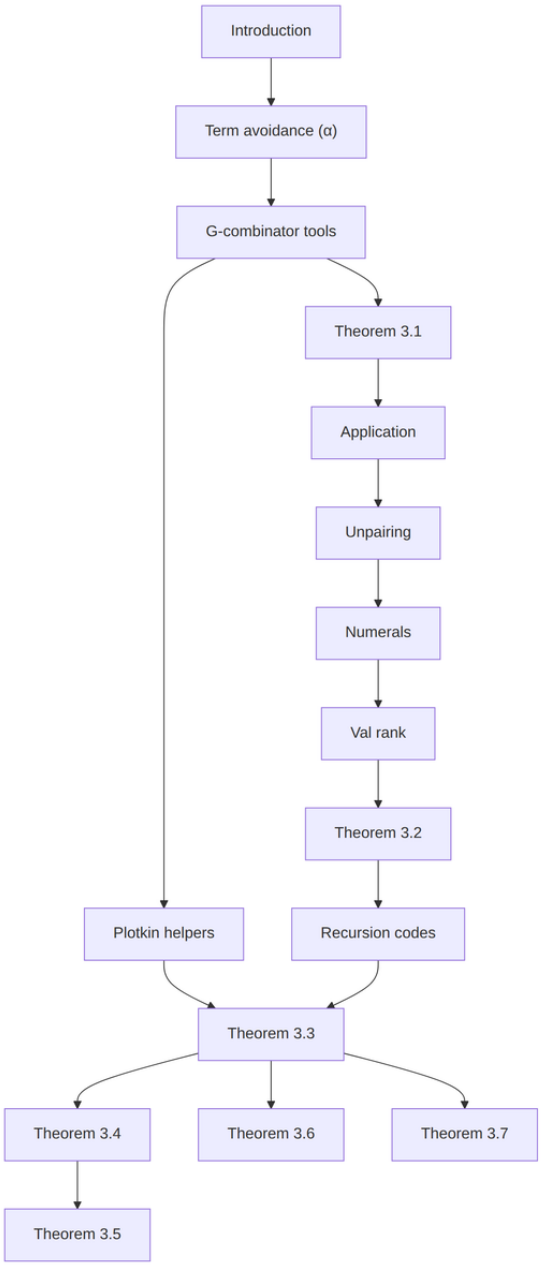

Figure 30: Enumeration and degrees.

3.4.1 Introduction ✓

Reduction to a few combinators is old in combinatory logic. The device special to this model is (3.1), which folds the arithmetical combinators into the one combinator $\mathbf{G}$. The Gödel numbering and the second recursion theorem are the standard constructions, written so that arithmetic and the type-free combinators share a

notation, and the incompleteness theorem is the standard one in that notation. Theorem 3.5 is the argument of [20]; Martin Hyland pointed out the connection. Theorem 3.6 restates enumeration degrees, as in [21], [22], and [23]. Scott notes that this area was underdeveloped beside the theory of Turing degrees. Semigroups of combinators had been discussed by Church and by Böhm, and Theorem 3.7 reads that discussion inside $\mathbf{RE} \cap \mathbf{FUN}$.

A great advantage of the combinators from the formal point of view is that (bound) variables are eliminated in favor of "algebraic" combinations. The disadvantage is that the algebra is not all that pretty, as the combinations tend to get rather long and general laws are rather few. Nevertheless as a technical device it is mildly remarkable that we can have a notation for all r.e. sets requiring so few primitives. In the model defined here the reduction to one combinator rests on a lemma about conditionals:

$$(3.1) \quad \mathbf{cond}(x)(y)(\mathbf{cond}(x)(y)) = y.$$

Recall that $\mathbf{cond}$ (or $\supset$) is a test for zero, so that:

$$(3.2) \quad \mathbf{cond}(x)(y)(0) = x.$$

This suggests that we lump all combinators of Theorem 2.4 into this one:

$$(3.3) \quad \mathbf{G} = \mathbf{cond}(\langle \mathbf{suc}, \mathbf{pred}, \mathbf{cond}, \mathbf{K}, \mathbf{S} \rangle)(0).$$

We can then readily prove Theorem 3.1 below.
(Already included: `1976_Avoids.md`.)

3.4.2 G-combinator tools ✓

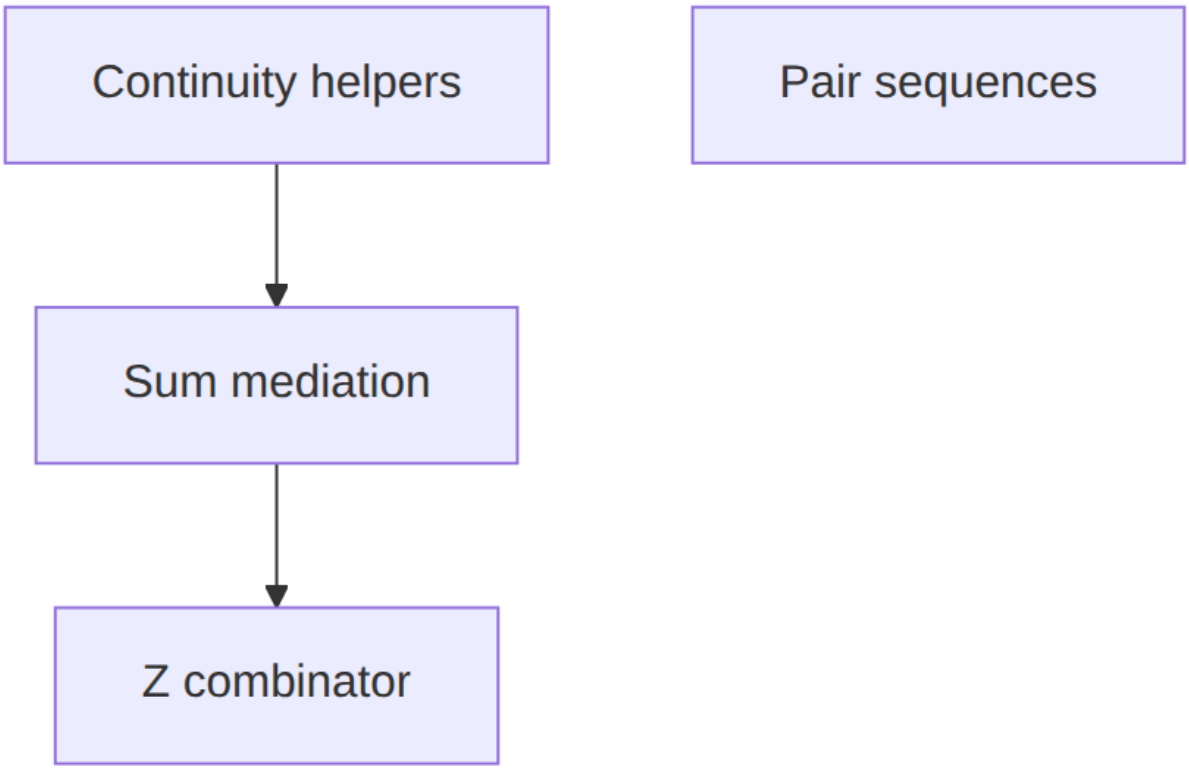

Figure 31: G-combinator tools ✓.

Continuity helpers ✓ Scott-continuity lemmas for diagonal and multi-argument composition.

Theorem (`ContinuityHelpers.on_diag`). If a binary map F is Scott-continuous in each argument separately, then $x \mapsto F(x, x)$ is Scott-continuous.

Proof. The diagonal substitution theorem identifies membership in $F(x, x)$ with a Scott-union over basic approximations $e_n \subseteq x$; translating that union into the Scott-union characterisation of continuity gives the claim. ■

Theorem (`ContinuityHelpers.tuple`). If F is Scott-continuous in each argument and g, h are Scott-continuous, then $x \mapsto F(g(x), h(x))$ is Scott-continuous.

Proof. Reduce to the diagonal case by fixing one composed argument and using substitution continuity of F along g or h. ■

Theorem (`ContinuityHelpers.nary`). If a ternary map F is Scott-continuous in each argument and g, h, i are Scott-continuous, then $x \mapsto F(g(x), h(x), i(x))$ is Scott-continuous.

Proof. Apply the tuple lemma in the first two slots with the third argument held by i, then close under diagonal continuity with substitution along i. ■

Sum mediation ✓ Tag successor σ_j and the mediating map out of a binary sum.

Definition (`sigmaJ`). $\sigma_j(x) = \{(j, k+1) \mid (j,k) \in x\}$.

Theorem (`sigmaJ.isScottContinuous`). Each σ_j is Scott-continuous.

Proof. A coded successor tag pulls a basic approximation containing the predecessor tag; conversely a Scott-union witness unpacks to such a predecessor. ■

Theorem (`sigmaJ.app`). $\mathrm{graph}(\sigma_j)\, x = \sigma_j(x)$.

Proof. The continuous-graph β-law. ■

Theorem (`sigmaJ.bot`). $\sigma_j(\bot) = \bot$.

Proof. The empty set contributes no tagged pairs. ■

Theorem (`sigmaJ.of_no_tag`). If u contains no pair with left tag j, then $\sigma_j(u) = \bot$.

Proof. Every member of $\sigma_j(u)$ would require such a predecessor tag. ■

Theorem (`sigmaJ.pair_union`). If $j \neq j'$, then $\sigma_j\big(\{(j,m)\} \cup \{(j',m)\}\big) = \{(j, m+1)\}$.

Proof. Only the matching tag survives; the other tag is excluded by distinctness. ■

Theorem (`sigmaJ.succ_ne`). If $j \neq j'$, then $\sigma_j(\{(j',m)\}) = \bot$.

Proof. A membership would force the tags equal. ■

Theorem (`sigmaJ.succ_singleton`). $\sigma_j(\{(j,m)\}) = \{(j, m+1)\}$.

Proof. Direct unpacking of the single tagged pair. ■

Theorem (`sigmaJ.union_fresh`). If u has no j-tag, then $\sigma_j\big(u \cup \{(j,m)\}\big) = \{(j, m+1)\}$.

Proof. Reorder the union and apply the singleton and no-tag cases. ■

Definition (`sumMed`). $\mathrm{sumMed}(f, g)$ is the graph of

$$u \mapsto \begin{cases} f(u_1) & \text{if } u_0 = 0, \\ g(u_1) & \text{otherwise,} \end{cases}$$

via the strict conditional on the zero and one projections of u.

Theorem (`sumMed.body_isScottContinuous`). That body map in u is Scott-continuous for fixed f and g.

Proof. Ternary continuity of the conditional along continuous projections and applications of f and g. ■

Theorem (`sumMed.app`). Applying $\mathrm{sumMed}(f, g)$ recovers the conditional body.

Proof. The β-law for the continuous body. ■

Theorem (`sumMed.app_inl`). $\mathrm{sumMed}(f, g)\, \langle 0, x\rangle = f(x)$.

Proof. Unfold application and the left injection projections. ■

Theorem (`sumMed.app_inr`). $\mathrm{sumMed}(f, g)\, \langle 1, x\rangle = g(x)$.

Proof. Symmetric with the right injection. ■

Theorem (`sumMed.isGraph`). $\mathrm{sumMed}(f, g)$ equals the graph of its own application.

Proof. Pointwise graph extension from $\mathrm{sumMed.app}$. ■

Theorem (`sumMed.rel`). If $f : A \to C$ and $g : B \to C$ as morphisms of restricted equivalences, then $\mathrm{sumMed}(f, g) : A + B \to C$.

Proof. Related sum elements are left or right injections; reduce via $\mathrm{sumMed.app_inl}$ or $\mathrm{sumMed.app_inr}$ to the assumed relatedness of f or g. ■

Theorem (`sumMed.rel_unique`). Any $h : A + B \to C$ that agrees with f on left injections and with g on right injections is related (as an arrow) to $\mathrm{sumMed}(f, g)$.

Proof. On related sum elements, rewrite h along the injection form and compare to the mediating applications of f or g. ■

Z combinator ✓ Finite iteration of application and its continuous combinator.

Definition (`Z`). For $n \in \mathbb{N}$, a map f, and an argument x,

$$Z(0, f, x) = x, \qquad Z(n+1, f, x) = f\big(Z(n, f, x)\big).$$

Theorem (`Z.rel`). If a restricted equivalence A is preserved by f versus f' on related arguments, and A relates x to y, then A relates $Z(n, f, x)$ to $Z(n, f', y)$.

Proof. Induction on n: the base is the given relatedness of x and y; the step applies the assumed preservation of A by f and f'. ■

Theorem (`Z.finite_bound`). Every member of $Z(m, e_p, e_q)$ is at most $\max(p, q)$.

Proof. Induction on m: the base uses the bound on members of e_q; the step unpacks a coded pair and uses the bound on the left factor from e_p. ■

Theorem (`Z.finite_no_tag`). The tagged pair $(\max(p, q) + 1,\ k)$ does not lie in $Z(m, e_p, e_q)$.

Proof. Any such membership would force $\max(p, q) + 1 \le \max(p, q)$ by the finite bound. ■

Theorem (`Z.graph_funOf`). Iterating the graph of $y \mapsto f(y)$ agrees with iterating f: $Z(n, \mathrm{graph}(y \mapsto f(y)), x) = Z(n, f, x)$.

Proof. Induction on n; the step uses the β-law for the continuous map f. ■

Theorem (`Z.isScottContinuous_left`). For fixed n and x, the map $f \mapsto Z(n, f, x)$ is Scott-continuous.

Proof. Induction on n: the base is a constant map; the step is continuous application of f to a continuous iterate, assembled by the tuple continuity helper. ■

Theorem (`Z.isScottContinuous_right`). For fixed n and f, the map $x \mapsto Z(n, f, x)$ is Scott-continuous.

Proof. Induction on n: the base is the identity; the step composes continuous application of f with the inductive iterate. ■

Definition (`Zcomb`). $\mathrm{Zcomb}(n) = \mathrm{graph}\big(f \mapsto \mathrm{graph}(x \mapsto Z(n, f, x))\big)$.

Theorem (`Zcomb.map_isScottContinuous`). The outer graph map $f \mapsto \mathrm{graph}(x \mapsto Z(n, f, x))$ is Scott-continuous.

Proof. Graph-constant continuity from the left continuity of Z in f. ■

Theorem (`Zcomb.app`). $\mathrm{Zcomb}(n)\ f = \mathrm{graph}(x \mapsto Z(n, f, x))$.

Proof. The β-law for the continuous outer map. ■

Theorem (`Zcomb.app2`). $\mathrm{Zcomb}(n)\ f\ x = Z(n, f, x)$.

Proof. Apply Zcomb.app, then the β-law for the continuous right iterate. ■

Theorem (`Zcomb.isGraph`). $\mathrm{Zcomb}(n)$ equals the graph of $f \mapsto \mathrm{Zcomb}(n)\ f$.

Proof. Pointwise graph extension using Zcomb.app. ■

Theorem (`Zcomb.app_isGraph`). $\mathrm{Zcomb}(n)\ f$ equals the graph of $x \mapsto \mathrm{Zcomb}(n)\ f\ x$.

Proof. From Zcomb.app and the β-law for the right iterate. ■

3.4.3 Theorem 3.1 ✓

THEOREM 3.1 (The generator theorem). *All LAMBDA-definable elements can be obtained from* **G** *by iterated application.*

A distributive function f is said to be *total* iff $f(n) \in \omega$ for all $n \in \omega$. As they come from obvious

primitive recursive functions, we do not stop to write out LAMBDA-definitions of these three total functions:

$$(3.4)\quad \mathbf{apply} = \lambda n \in \omega.\, \lambda m \in \omega.\, (n, m) + 1$$

$$(3.5)\quad \mathbf{op}((n, m)) = n$$

$$(3.6)\quad \mathbf{arg}((n, m)) = m.$$

The point of these auxiliary combinators concerns our Gödel numbering of the r.e. sets. The number 0 will correspond to the generator $\mathbf{G}$; while $(n, m) + 1$ will correspond to the application of the nth set to the mth. This is formalized in the combinator $\mathbf{val}$ which is defined as the least fixed point of the equation:

$$(3.7)\quad \mathbf{val} = \lambda k \in \omega.\, k \supset \mathbf{G},\ \mathbf{val}(\mathbf{op}(k - 1))(\mathbf{val}(\mathbf{arg}(k - 1))).$$

This function accomplishes the enumeration as follows:

Theorem 3.1 is obvious from the construction of $\mathbf{G}$, because $\mathbf{G}(\mathbf{G}) = 0$ and $\mathbf{G}(0)(0) = \mathbf{suc}$, and so the $\mathbf{G}(0)(i)$ give us all the other combinators.

Formalization. Combinatory elements are those built from the base combinators $\mathbf{0}$, $\mathbf{suc}$, $\mathbf{pred}$, $\mathbf{cond}$, $\mathbf{K}$, $\mathbf{S}$ by application. Generation from $\mathbf{G}$ is the inductive closure of $\{\mathbf{G}\}$ under application. The generator theorem equates the two.

Theorem (`theorem_3_1`). An element is combinatory if and only if it is generated from $\mathbf{G}$ by iterated application.

Proof. ($\Rightarrow$) By induction on the combinatory construction: $\mathbf{0} = \mathbf{G}(\mathbf{G})$ and $\mathbf{suc} = \mathbf{G}(0)(0)$, so both lie in the $\mathbf{G}$-closure; the remaining base combinators are obtained by further applications of $\mathbf{G}$ to 0 and $1 = \mathbf{suc}(0)$ as in the generator identities; the inductive step is closure under application. ($\Leftarrow$) By induction on generation from $\mathbf{G}$: $\mathbf{G}$ itself is combinatory, and the combinatory class is closed under application. ■

3.4.4 Application ✓

Scott codes application of combinators by operations on integers. After Theorem 3.1 he introduces three total (primitive recursive) functions used in the Gödel numbering of r.e. sets; the integer form of application is the first, and the two projections of Cantor pairing are the others. As they come from obvious primitive recursive functions, the paper does not write out LAMBDA-definitions. The point of these auxiliaries is that

0 will correspond to the generator $\mathbf{G}$, while $(n, m) + 1$ will correspond to applying the nth set to the mth.

Definition (`applyNat`, equation (3.4)). For $n, m \in \omega$,

$$\mathrm{applyNat}(n, m) = (n, m) + 1,$$

where (n, m) is Cantor pairing (`pair`). This is the integer form of $\mathbf{apply}(n)(m)$.

Definition (`opNat`, equation (3.5)). $\mathrm{opNat}(k) = (\mathrm{unpair}\, k)_1$. On a coded pair this recovers the first component, so $\mathbf{op}((n, m)) = n$.

Definition (`argNat`, equation (3.6)). $\mathrm{argNat}(k) = (\mathrm{unpair}\, k)_2$. On a coded pair this recovers the second component, so $\mathbf{arg}((n, m)) = m$.

Theorem (`eq_3_5`). For all $n, m \in \omega$, $\mathrm{opNat}((n, m)) = n$.

Proof. Unfold `opNat` and apply `unpair_pair`: $\mathrm{unpair}((n, m)) = (n, m)$. ■

Theorem (`eq_3_6`). For all $n, m \in \omega$, $\mathrm{argNat}((n, m)) = m$.

Proof. Unfold `argNat` and apply `unpair_pair`. ■

Theorem (`eq_3_8_apply`, first half of (3.8)). $\mathrm{applyNat}(0, 0) = 1$.

Proof. $(0, 0) = 0$, so $(0, 0) + 1 = 1$. ■

Theorem (`eq_3_9_apply`, first half of (3.9)). $\mathrm{applyNat}(0, 1) = 3$.

Proof. $(0, 1) = 2$, so $(0, 1) + 1 = 3$. ■

Theorem (`eq_3_10_apply`, first half of (3.10)). $\mathrm{applyNat}(3, 1) = 12$.

Proof. $(3, 1) = 11$, so $(3, 1) + 1 = 12$. ■

These three special cases are the integer codes later used for numerals and $\mathbf{val}$: by (3.8)–(3.10) one has $\mathbf{val}(1) = 0$, $\mathbf{val}(3) = \langle \mathbf{suc}, \ldots \rangle$, and $\mathbf{val}(12) = \mathbf{suc}$.

3.4.5 Unpairing ✓

Cantor pairing is inverted by locating the least triangle bucket that contains a code and reading off the residual. The formalization uses a search lemma and two equivalent presentations of that search, then defines the computational unpair map.

Definition (`triangle`, from `pair.lean`). $\mathrm{triangle}(w) = w(w+1)/2$. The codes with diagonal sum w occupy the half-open interval $[\mathrm{triangle}(w),\ \mathrm{triangle}(w+1))$.

Definition (`unpairWRec`). Recursion on n: $\mathrm{unpairWRec}(k, 0) = 0$, and

$$\mathrm{unpairWRec}(k, n+1) = \begin{cases} \mathrm{unpairWRec}(k, n) & \text{if } k < \mathrm{triangle}(n+1), \\ n+1 & \text{otherwise.} \end{cases}$$

This advances the candidate bucket until k lies below $\mathrm{triangle}(w+1)$.

Definition (`unpairW`). $\mathrm{unpairW}(k) = \mathrm{unpairWRec}(k, k)$.

Definition (`unpairComp`). With $w = \mathrm{Nat.find}(\mathrm{exists_triangle_succ}\, k)$ and $m = k - \mathrm{triangle}(w)$, set $\mathrm{unpairComp}(k) = (w - m,\ m)$.

Theorem (`exists_triangle_succ`). For every $k \in \omega$ there is a w with $k < \mathrm{triangle}(w+1)$.

Proof. Take $w = k$. Then $\mathrm{triangle}(k+1) = \mathrm{triangle}(k) + (k+1)$, so $k < k+1 \le \mathrm{triangle}(k+1)$. ■

Theorem (`unpairWRec.succ`). Unfolding the successor step:

$$\mathrm{unpairWRec}(k, n+1) = \begin{cases} \mathrm{unpairWRec}(k, n) & \text{if } k < \mathrm{triangle}(n+1), \\ n+1 & \text{otherwise.} \end{cases}$$

Proof. By definition of `Nat.rec`. ■

Theorem (`unpairWRec.lt`). For all k, n, either $k < \mathrm{triangle}(\mathrm{unpairWRec}(k, n) + 1)$ or $\mathrm{unpairWRec}(k, n) = n$.

Proof. Induction on n. At 0, case-split on $k < \mathrm{triangle}(1)$. At $n+1$, if $k < \mathrm{triangle}(n+1)$ then the recursive value inherits the claim from the inductive hypothesis (and if that value equals n, the same inequality $k < \mathrm{triangle}(n+1)$ applies); otherwise the value is $n+1$. ■

Theorem (`unpairWRec.min`). If $m < \mathrm{unpairWRec}(k, n)$, then $\neg(k < \mathrm{triangle}(m+1))$.

Proof. Induction on n, generalizing m. At 0 the hypothesis $m < \mathrm{unpairWRec}(k, 0)$ is impossible. At $n+1$, if $k < \mathrm{triangle}(n+1)$ reduce to the inductive hypothesis; otherwise $\mathrm{unpairWRec}(k, n+1) = n+1$, so $m \le n$, and any $k < \mathrm{triangle}(m+1)$ would force $k < \mathrm{triangle}(n+1)$ by monotonicity of triangle, a contradiction. ■

Theorem (`unpairW.eq`). $\mathrm{unpairW}(k) = \mathrm{Nat.find}(\mathrm{exists_triangle_succ}\, k)$.

Proof. Show $\mathrm{unpairWRec}(k, k)$ satisfies the characterizing properties of Nat.find: it is a witness (`unpairWRec.lt`, using $k+1 \le \mathrm{triangle}(k+1)$ when the residual case $\mathrm{unpairWRec}(k, k) = k$ occurs), and no smaller index works (`unpairWRec.min`). ■

Theorem (`unpairComp.eq`). $\mathrm{unpairComp}(k) = \mathrm{unpair}(k)$.

Proof. Let w be that find-witness and $m = k - \mathrm{triangle}(w)$. Minimality of w gives $\mathrm{triangle}(w) \le k$, and $k < \mathrm{triangle}(w+1)$ gives $m \le w$. Then $(w - m) + m = w$, so $\mathrm{pair}(w - m,\ m) = k$ by the triangle form of pairing. Apply `unpair_pair`. ■

3.4.6 Numerals ✓

The numeral for each integer is built by iterating application, starting from the code of zero.

Definition (num, (3.11)). $\mathrm{num}(0) = 1$ and $\mathrm{num}(n+1) = \mathrm{applyNat}(12, \mathrm{num}(n))$. By (3.8) and (3.10),

1 is the code of 0 and 12 is the code of successor, so $\mathrm{num}(n)$ is the code of the numeral for n.

num.lean

```
module

  | n + 1 => applyNat 12 (num n)

end DomainTheory.DataTypesAsLattices
```

3.4.7 Val rank ✓

The enumeration **val** is defined by recursion on application codes. Rank measures the depth of that recursion, and bit lists collect the one-bits of a code when scanning finite approximations.

Definition (`valRank`). $\mathrm{valRank}(0) = 1$, and for a positive code $p + 1$ the rank is one more than the maximum of the ranks of the two Cantor components of p.

Definition (`bitList`). $\mathrm{bitList}(j)$ is the list of indices $k \leq j$ for which the kth bit of j is set.

Definition (`Extensional`). A map p on codes is extensional relative to an enumeration val when $\mathrm{val}(n) = \mathrm{val}(m)$ implies $\mathrm{val}(p(n)) = \mathrm{val}(p(m))$. Theorem 3.5 uses this for $\mathrm{val} = \mathbf{val}$.

end DomainTheory.DataTypesAsLattices
```

3.4.8 Theorem 3.2 ✓

THEOREM 3.2 (The enumeration theorem). *The combinator* **val** *enumerates the LAMBDA-definable elements in that* $\mathbf{RE} = \{\mathbf{val}(n) \mid n \in \omega\}$. *Further:*

(i) $\mathbf{val}(0) = \mathbf{G}$,

(ii) $\mathbf{val}(\mathbf{apply}(n)(m)) = \mathbf{val}(n)(\mathbf{val}(m))$.

As a principal application of the Enumeration Theorem we may mention the following: suppose u is given as LAMBDA-definable. We look at its definition and rewrite it in terms of combinators—eventually in terms of $\mathbf{G}$ alone. Then using 0 and **apply** we write down the name of an integer corresponding to the combination—say, n. By Theorem 3.2 we see that we have *effectively found* from the definition an integer such that $\mathbf{val}\, n = u$. This remark can be strengthened by some numerology.

Formalization. Scott's (i)–(ii) and the set equality $\mathbf{RE} = \{\mathbf{val}(n)\}$ are assembled in `theorem_3_2.lean` from the recursive enumerator `valNat` (equation (3.7)) and Theorem 3.1. Each name below is the Lean theorem; proofs live in that module.

Theorem (`theorem_3_2`). For every n, $\mathrm{valNat}(n) \in \mathbf{RE}$; $\mathrm{valNat}(0) = \mathbf{G}$; and for all n, m,

$$\mathrm{valNat}(\mathrm{applyNat}(n, m)) = \mathrm{valNat}(n) \cdot \mathrm{valNat}(m).$$

Proof. Package three library facts on `valNat`: `valNat.combinatory` (every value is combinatory, hence in $\mathbf{RE}$), `valNat.zero`, and `valNat.app`. ■

Theorem (`theorem_3_2.surjective`). If u is combinatory, then $\exists n.\ \mathrm{valNat}(n) = u$.

Proof. By Theorem 3.1, combinatory elements are exactly those generated from $\mathbf{G}$ by application. Induct on that generation: $\mathbf{G}$ is $\mathrm{valNat}(0)$; if $u = \mathrm{valNat}(n)$ and $v = \mathrm{valNat}(m)$, then $u \cdot v = \mathrm{valNat}(\mathrm{applyNat}(n, m))$ by `valNat.app`. ■

Theorem (`theorem_3_2.i`). $\mathrm{condSet}(0, \mathbf{G}, \bot) = \mathbf{G}$.

Proof. Extensionality on membership. Left-to-right: a member of the conditional is either in $\mathbf{G}$ on the true branch, or comes from a witness that $0 \in 0$, which is impossible. Right-to-left: every member of $\mathbf{G}$ sits on the true branch. ■

Theorem (`theorem_3_2.range`). $\mathbf{RE} = \mathrm{Set.range}\ \mathrm{valNat}$.

Proof. If $u \in \mathbf{RE}$, then u is combinatory, so `surjective` supplies a preimage. Conversely, every $\mathrm{valNat}(n)$ lies in $\mathbf{RE}$ by the first conjunct of `theorem_3_2`. ■

```

3.4.10 Plotkin helpers ✓

Finite Plotkin steps: normalized application of e_p, tagging via σ_j, and iterated predecessors on numerals.

Theorem (`PlotkinHelpers.normalized_finite_app`). Applying the graph of $y \mapsto e_p(y)$ recovers e_p itself: $\mathrm{graph}(y \mapsto e_p(y))\, u = e_p(u)$.

Proof. The β-law for continuous application of e_p. ■

Theorem (`PlotkinHelpers.normalized_finite_fresh_app`).

$$\mathrm{graph}(y \mapsto e_p(y))\big(Z(m, e_p, e_q) \cup \{(\max(p,q)+1,\ m)\}\big) = Z(m+1, e_p, e_q).$$

Proof. Reduce by the normalized β-law, then discard the fresh tag by the union-fresh application of e_p. ■

Theorem (`PlotkinHelpers.finite_sigma_plain_app`).

$$\big(\mathrm{graph}(y \mapsto e_p(y)) \cup \mathrm{graph}(\sigma_{\max(p,q)+1})\big)\, Z(m, e_p, e_q) = Z(m+1, e_p, e_q).$$

Proof. Split the union application; the normalized part iterates once, while σ_j on $Z(m, e_p, e_q)$ is empty by the finite no-tag bound. ■

Theorem (`PlotkinHelpers.finite_sigma_union_app`).

$$\begin{aligned}&\big(\mathrm{graph}(y \mapsto e_p(y)) \cup \mathrm{graph}(\sigma_{\max(p,q)+1})\big)\big(Z(m, e_p, e_q) \cup \{(\max(p,q)+1,\ m)\}\big)\\ &\quad = Z(m+1, e_p, e_q) \cup \{(\max(p,q)+1,\ m+1)\}.\end{aligned}$$

Proof. Split the union: the normalized fresh step yields the next iterate, and σ_j on the fresh singleton advances the tag. ■

Theorem (`PlotkinHelpers.predSet_iterate_expTag_isScottContinuous`). For each k, the map $e \mapsto \mathrm{predSet}^k(e(0))$ is Scott-continuous.

Proof. Induction on k: the base is left-continuity of application at 0; the step composes continuous predSet with the inductive map. ■

Theorem (`PlotkinHelpers.predSet_iterate_ofNat`). $\mathrm{predSet}^k(\overline{k+i}) = \overline{i}$.

Proof. Induction on k: the base is immediate; the step uses the successor law for predSet on numerals. ■

Theorem (`PlotkinHelpers.predSet_iterate_self`). $\mathrm{predSet}^k(\overline{k}) = \overline{0}$.

Proof. The previous identity at $i = 0$. ■

3.4.11 Theorem 3.3 ✓

THEOREM 3.3 (The second recursion theorem). Take a LAMBDA-definable element v such that:

(i) $\mathbf{val}(v(n)) = \lambda m \in \omega.\, \mathbf{val}(n)(\mathbf{apply}(m)(\mathbf{num}(m)))$,

and then define a combinator by:

(ii) $\mathbf{rec} = \lambda n \in \omega.\, \mathbf{apply}(v(n))(\mathbf{num}(v(n)))$.

Then we have a primitive recursive function with this fixed-point property:

(iii) $\mathbf{val}(\mathbf{rec}(n)) = \mathbf{val}(n)(\mathbf{rec}(n))$.

Note that if u is LAMBDA-definable, then we find first an n such that $\mathbf{val}(n) = u$. Next we calculate $k = \mathbf{rec}(n)$. This effectively gives us an integer such that $\mathbf{val}(k) = u(k)$. Gödel numbers represent expressions (combinations in $\mathbf{G}$), and $\mathbf{val}$ maps the numbers to the values denoted by the expressions in the model. The k just found thus represents an expression whose value is defined in terms of its own Gödel number. In recursion theory there are many applications of this result.

Formalization. Write $S(u)$ for the continuous function $\lambda x.\, \bigcup_{m \in x} u(\mathbf{apply}(m)(\mathbf{num}(m)))$, so Scott's right-hand side in (i) is $S(\mathbf{val}(n))$. A concrete total primitive recursive v is obtained by applying a fixed code for the operator $u \mapsto S(u)$ to n. The recursion code is $\mathbf{rec}(n) = \mathbf{apply}(v(n))(\mathbf{num}(v(n)))$ as in

(ii). A parallel self-application uses $\mathbf{Y}$: the code $\mathbf{apply}(\mathbf{Ycode}, n)$ satisfies $\mathbf{val}(\mathbf{apply}(\mathbf{Ycode}, n)) = \mathbf{val}(n)(\mathbf{val}(\mathbf{apply}(\mathbf{Ycode}, n)))$.

Theorem (`theorem_3_3.from_v`). Suppose $\mathbf{val}(v(n)) = S(\mathbf{val}(n))$. Setting $\mathbf{rec}(n) = \mathbf{apply}(v(n))(\mathbf{num}(v(n)))$, one has

$$\mathbf{val}(\mathbf{rec}(n)) = \mathbf{val}(n)(\mathbf{rec}(n)).$$

Proof. By the enumeration theorem, $\mathbf{val}(\mathbf{apply}(v(n))(\mathbf{num}(v(n)))) = \mathbf{val}(v(n))(\mathbf{val}(\mathbf{num}(v(n))))$. The hypothesis replaces the operator by $S(\mathbf{val}(n))$, and (3.12) gives $\mathbf{val}(\mathbf{num}(v(n))) = v(n)$. Unfolding S yields a union of applications of $\mathbf{val}(n)$ indexed by members of the numeral $v(n)$; that numeral is the singleton $\{v(n)\}$ in the coding, so the union reduces to the single term $\mathbf{val}(n)(\mathbf{apply}(v(n))(\mathbf{num}(v(n)))) = \mathbf{val}(n)(\mathbf{rec}(n))$. ■

Theorem (`theorem_3_3.i`). For the concrete v above, $\mathbf{val}(v(n)) = S(\mathbf{val}(n))$ for every n.

Proof. By construction $v(n)$ is the application of the code of the operator $u \mapsto S(u)$ to n. The enumeration theorem and the defining equation of that operator give $\mathbf{val}(v(n)) = S(\mathbf{val}(n))$. ■

Theorem (`theorem_3_3.ii`). For every total v and every n,

$$\mathbf{rec}(n) = \mathbf{apply}(v(n))(\mathbf{num}(v(n))).$$

Proof. This is the definition of $\mathbf{rec}$ in (ii). ■

Theorem (`theorem_3_3.val`). Writing $r(n) = \mathbf{apply}(\mathbf{Ycode}, n)$, one has

$$\mathbf{val}(r(n)) = \mathbf{val}(n)(\mathbf{val}(r(n))).$$

Proof. By the enumeration theorem, $\mathbf{val}(r(n)) = \mathbf{val}(\mathbf{Ycode})(\mathbf{val}(n))$. The code $\mathbf{Ycode}$ evaluates to the combinator $\mathbf{Y}$, and the fixed-point law for $\mathbf{Y}$ supplies $\mathbf{Y}(\mathbf{val}(n)) = \mathbf{val}(n)(\mathbf{Y}(\mathbf{val}(n)))$. ■

Theorem (`theorem_3_3`). There is a total primitive recursive v such that $\mathbf{rec}$ defined by (ii) is primitive recursive, (i) holds for this v, and (iii) holds for the corresponding $\mathbf{rec}$.

Proof. Take the concrete v of the preceding construction (application of the code of $u \mapsto S(u)$). It is primitive recursive, as is $\mathbf{rec}$ formed from it by pairing with $\mathbf{num}$. Clause (i) is the theorem just proved for this v; clause (ii) is the definition of $\mathbf{rec}$; clause (iii) follows from the general fixed-point lemma once (i) is known. ■

3.4.12 Theorem 3.4 ✓

THEOREM 3.4 (The incompleteness theorem). The set of integers n such that $\mathbf{val}(n) = \perp$ is not r.e.; hence, there can be no effectively given formal system for enumerating all true equations between LAMBDA-terms.

(A critic may sense here an application of Church's thesis in stating the metatheoretic consequence of the nonresult.) A few details of the proof can be given to see how the notation works. First let v be a (total) primitive recursive function such that:

$$\mathbf{val}(v(n)) = n \cap \mathbf{val}(n),$$

and note that:

$$n \cap \mathbf{val}(n) = \bot \quad \text{iff} \quad n \notin \mathbf{val}(n).$$

Call the set in question in Theorem 3.4 the set b. If it were r.e., then so would be:

$$\{n \in \omega \mid v(n) \in b\} = (\lambda n \in \omega.\, v(n) \cap b \supset n, n)(\top).$$

That would mean having an integer k such that:

$$\mathbf{val}(k) = \{n \in \omega \mid v(n) \in b\}.$$

But then:

$$\begin{aligned} k \in \mathbf{val}(k) &\iff v(k) \in b \\ &\iff \mathbf{val}(v(k)) = \bot \\ &\iff k \notin \mathbf{val}(k), \end{aligned}$$

which gives us a contradiction. This is the usual diagonal argument.

3.4.13 Theorem 3.5 ✓

The relationship $\mathbf{val}(n) = \mathbf{val}(m)$ means that the expressions with Gödel numbers n and m have the same value in the model. (This is not only not r.e. but is a complete Π^0_2-predicate.) A *total* mapping can be regarded as a *syntactical* transformation on expressions defined via Gödel numbers. Such a mapping p is called *extensional* if it has the property:

$$\mathbf{val}(p(n)) = \mathbf{val}(p(m)) \quad \text{whenever} \quad \mathbf{val}(n) = \mathbf{val}(m).$$

The Myhill–Shepherdson theorem shows that extensional, syntactical mappings really depend on the *values* of the expressions. Precisely we have:

THEOREM 3.5 (The completeness theorem for definability). *If a (total) extensional mapping p is LAMBDA-definable, then there is a LAMBDA-definable q such that $\mathbf{val}(p(n)) = q(\mathbf{val}(n))$ for all $n \in \omega$.*

Of course q is uniquely determined (because the values of q are given at least on the finite sets). Thus any attempt to define something *new* by means of some strange mapping on Gödel numbers is bound to fail as long as it is *effective* and *extensional*. The main part of the argument is concentrated on showing these mappings to be *continuous*; that is why q exists.

Proof of Theorem 3.5. The argument is essentially the original one of Myhill–Shepherdson. Suppose p is computable, total and extensional. Define:

$$q = \{(j, m) \mid m \in \mathbf{val}(p(\mathbf{fin}(j)))\},$$

where $\mathbf{fin}$ is primitive recursive, and for all $j \in \omega$:

$$\mathbf{val}(\mathbf{fin}(j)) = e_j.$$

Certainly $q \in \mathbf{RE}$, and we will establish the theorem if we can prove "continuity":

$$\mathbf{val}(p(n)) = \bigcup\{\mathbf{val}(p(\mathbf{fin}(j))) \mid e_j \subseteq \mathbf{val}(n)\}.$$

We proceed by contradiction. Suppose first we have a $k \in \mathbf{val}(p(n))$, where $k \notin \mathbf{val}(p(\mathbf{fin}(j)))$ whenever $e_j \subseteq \mathbf{val}(n)$. Pick r to be a primitive recursive function whose range is *not* recursive. Define s, primitive recursive, so that for all $m \in \omega$:

$$\mathbf{val}(s(m)) = \{j \in \mathbf{val}(n) \mid m \notin \{r(i) \mid i \leq j\}\}.$$

The set $\mathbf{val}(n)$ must be infinite, because p is extensional, and if $\mathbf{val}(n) = e_j = \mathbf{val}(\mathbf{fin}(j))$, then $k \notin \mathbf{val}(p(\mathbf{fin}(j))) = \mathbf{val}(p(n))$. Note that $\mathbf{val}(s(m))$, as a subset of the infinite set, is *finite* if m is in the range of r; otherwise it is equal to $\mathbf{val}(n)$. Again by the extensionality of p we see that $k \in \mathbf{val}(p(s(m)))$ if and only if m is *not* in the range of r. But this puts an r.e. condition on m equivalent to a non-r.e. condition, which shows there is no such k.

For the second case suppose we have a $k \notin \mathbf{val}(p(n))$, where for a suitable $e_j \subseteq \mathbf{val}(n)$ it is the case that $k \in \mathbf{val}(p(\mathbf{fin}(j)))$. Define:

$$t = \lambda m \in \omega.\, e_j \cup (\mathbf{val}(m) \supset \mathbf{val}(n), \mathbf{val}(n)).$$

We have:

$$t(m) = \begin{cases} e_j & \text{if } \mathbf{val}(m) = \bot; \\ \mathbf{val}(n) & \text{if not.} \end{cases}$$

We choose u primitive recursive, where:

$$\mathbf{val}(u(m)) = t(m).$$

By the choice of k, and by the extensionality of p, and by the fact that $\mathbf{val}(n) \neq e_j$, we have:

$$k \in \mathbf{val}(p(u(m))) \quad \text{iff} \quad t(m) = e_j$$
$$\text{iff} \quad \mathbf{val}(m) = \bot.$$

But this is impossible, since one side is r.e. in m and the other is not by Theorem 3.4. As both cases lead to contradiction, continuity is established and the proof is complete.

Formalization. Write $\mathbf{fin}(j)$ for a code of the finite set e_j, and write

$$Q = \{(j, m) \mid m \in \mathbf{val}(p(\mathbf{fin}(j)))\}$$

for Scott's q. Continuity is the equality $\mathbf{val}(p(n)) = Q(\mathbf{val}(n))$, proved by ruling out the two failure modes below. The enumerator's range of a fixed non-recursive primitive recursive r plays the role of Scott's $\{r(i)\}$.

Theorem (`theorem_3_5.case1`). Let p be realized by a combinatory element and be extensional for $\mathbf{val}$. Suppose $k \in \mathbf{val}(p(n))$ yet $k \notin \mathbf{val}(p(\mathbf{fin}(j)))$ whenever $e_j \subseteq \mathbf{val}(n)$, and suppose $\mathbf{val}(n)$ is infinite. Then contradiction.

Proof. Form the primitive recursive s of Scott's first case (filter $\mathbf{val}(n)$ against the initial segment of the range of r up to stage j). Extensionality yields $k \in \mathbf{val}(p(s(m)))$ if and only if m lies outside the range of r. The left-hand side is an r.e. predicate of m (membership of a fixed k after composing the realizer of p with s), while the complement of the range of r is not r.e. ■

Theorem (`theorem_3_5.case2`). Under the same hypotheses on p, suppose $e_j \subseteq \mathbf{val}(n)$, $e_j \neq \mathbf{val}(n)$, $k \in \mathbf{val}(p(\mathbf{fin}(j)))$, and $k \notin \mathbf{val}(p(n))$. Then contradiction.

Proof. Form Scott's $t(m)$ (equal to e_j when $\mathbf{val}(m) = \bot$, and to $\mathbf{val}(n)$ otherwise) and a primitive recursive code u with $\mathbf{val}(u(m)) = t(m)$. Extensionality gives $k \in \mathbf{val}(p(u(m)))$ if and only if $\mathbf{val}(m) = \bot$. The left side is r.e. in m; the right side is not, by Theorem 3.4. ■

Theorem (`theorem_3_5.q`). $(j, m) \in Q$ if and only if $m \in \mathbf{val}(p(\mathbf{fin}(j)))$.

Proof. Immediate from the definition of Q as a set of coded pairs. ■

Theorem (`theorem_3_5.q_app`). $\mathbf{val}(p(\mathbf{fin}(j))) \subseteq Q(e_j)$.

Proof. Every $m \in \mathbf{val}(p(\mathbf{fin}(j)))$ contributes the pair (j, m) to Q, and $j \in e_j$. ■

Theorem (`theorem_3_5.unique`). If q and q' are Scott-continuous and agree on every finite e_n, then $q = q'$ as maps on $\mathbf{P}\omega$.

Proof. Every x is the directed union of the finite $e_n \subseteq x$; continuity and agreement on those pieces give $q(x) = q'(x)$. ■

Theorem (`theorem_3_5.of_realizer`). If $\mathbf{val}(p(n)) = q(\mathbf{val}(n))$ holds for all n, then that same family of equations holds for all n.

Proof. Immediate. ■

Theorem (`theorem_3_5`). If a total p is LAMBDA-definable and extensional for $\mathbf{val}$, then there is a LAMBDA-definable q with $\mathbf{val}(p(n)) = q(\mathbf{val}(n))$ for all n.

Proof. Take $q = Q$ as above; it is r.e., hence combinatory. For membership of k in $\mathbf{val}(p(n))$ versus $Q(\mathbf{val}(n))$, the two directions reduce to the continuity equation. Failure of either inclusion produces one of the two contradictory configurations already ruled out. ■

3.4.14 Theorem 3.6 ✓

The preceding results indicate that the expected results on r.e. sets are forthcoming in a smooth and unified manner in this setting. Some knowledge of r.e. theory was presupposed, but analysis shows that the knowledge required is slight. The notion of primitive recursive functions should certainly be well understood together with standard examples. Partial functions need not be introduced separately since they are naturally incorporated into LAMBDA (the theory of multiple-valued functions). As a working definition of r.e. one can take either "empty or the range of a primitive recursive function" or, more uniformly, "a set of the form $\{m \mid \exists n.\, m + 1 = p(n)\}$ where p is primitive recursive". A few obvious closure properties of r.e. sets should then be proved, and then an adequate foundation for the discussion of LAMBDA will have been provided.

The point of introducing LAMBDA is that further closure properties are more easily expressed in a theory where equations can be variously interpreted as involving numbers, functionals, etc., without becoming too heavily involved in intricate Gödel numbering and encodings. Another useful feature of the present theory concerns the ease with which we can introduce *relative recursiveness*.

As we have seen, $\{\mathbf{val}(n) \mid n \in \omega\}$ is an enumeration of all r.e. sets. Suppose we add a new set a as a new constant. What are the sets enumerable in a? Answer: $\{\mathbf{val}(n)(a) \mid n \in \omega\}$, since in combinatory logic a parameter can always be factored out as an extra argument. Another way to put the point is this: for b to be enumeration reducible to a it is necessary and sufficient that $b = u(a)$ where $u \in \mathbf{RE}$. This is *word for word* the definition given by [21, pp. 146–147]. What we have done is to put the theory of enumeration operators (Friedberg–Rogers and Myhill–Shepherdson) into a general setting in which the language LAMBDA not only provides definitions but also the basis of a calculus for demonstrating properties of the operators defined. The algebraic style of this language throws a little light on the notion of enumeration degree. In the first place we can identify the degree of an element with the set of all objects reducible to it (rather than just those equivalent to it) and write

$$\mathbf{Deg}(a) = \{u(a) \mid u \in \mathbf{RE}\}.$$

The set-theoretical inclusion is then the same as the partial ordering of degrees. What kind of a partially ordered set do we have?

THEOREM 3.6 (The subalgebra theorem). *The enumeration degrees are exactly the finitely generated combinatory subalgebras of* $\mathbf{P}\omega$.

By "subalgebras" here we of course mean subsets containing $\mathbf{G}$ and closed under application (hence, they contain all of $\mathbf{RE}$, the least subalgebra). Part of the assertion is that every finitely generated subalgebra has a single generator (under application). This fact is an easy extension of Theorem 3.1. Not very much seems to be known about enumeration degrees. Joins can obviously be formed using the pairing function $\langle x, y\rangle$ on sets. Each degree is a countable set; hence, it is trivial to obtain the existence of a sequence of degrees whose *infinite join* is not a degree (not finitely generated). The intersection of subalgebras is a subalgebra—but it may not be a degree even starting with degrees. There are no minimal degrees above $\mathbf{RE}$, but there are minimal *pairs* of degrees. Also for a given degree there are only countably many degrees minimal over it; but the question of whether the partial ordering of enumeration degrees is dense seems still to be open.

Theorem 3.6 shows that the semilattice of enumeration degrees is naturally extendable to a *complete lattice* (the lattice of all subalgebras of $\mathbf{P}\omega$), but whether there is anything interesting to say about this complete lattice from the point of view of structure is not at all clear. Rogers has shown [21, pp. 151–153] that Turing degrees can be defined in terms of enumeration degrees by restricting to special elements. In our style of notation we would define the space:

$$\mathbf{TOT} = \{u \mid u = \$(u) \text{ and } \forall n \in \omega.\, u(n) \in \omega\},$$

the space of all graphs of total functions. Then the system $\{\mathbf{Deg}(u) \mid u \in \mathbf{TOT}\}$ is isomorphic to the system of Turing degrees. Now there are many other interesting subsets of $\mathbf{P}\omega$. Whether the degree structure of these various subsets is worth investigation is a question whose answer awaits some new ideas.

Proof of Theorem 3.6. Consider a degree $\mathbf{Deg}(a)$. This set is closed under application, because:

$$u(a)(v(a)) = \mathbf{S}(u)(v)(a),$$

and $\mathbf{S}(u)(v)$ is r.e. if both u and v are. Note that it also contains the element $\mathbf{G}$; hence, as a subalgebra, it is generated by a and $\mathbf{G}$.

Let A be any finitely generated subalgebra with generators $a'_0, a'_1, \ldots, a'_{n-1}$. Consider the element $a = \mathbf{cond}(\langle a'_0, a'_1, \ldots, a'_{n-1}\rangle)(\mathbf{G})$. As in the proof of Theorem 3.1, a generates A under application. It is then easy to see why $\mathbf{A} = \mathbf{Deg}(a)$.

Formalization. Write $\mathbf{Deg}(a) = \{r(a) \mid r \in \mathbf{RE}\}$ as above. Pack a finite list of generators into a single sequence element $\langle a'_0, \ldots, a'_{n-1}\rangle$ by iterating the binary sequence constructor, and form Scott's single generator

$$a = \mathbf{cond}(\langle a'_0, \ldots, a'_{n-1}\rangle)(\mathbf{G}).$$

(Thus $a(0) = \langle a'_0, \ldots\rangle$ and a still lies in any subalgebra containing the a'_i and $\mathbf{G}$.) The three lemmas below are the pieces of Scott's argument recorded in this note's Lean module.

Theorem (`theorem_3_6.degree`). For every a, the set $\mathbf{Deg}(a)$ is a combinatory subalgebra and contains a.

Proof. Closure under application is the $\mathbf{S}$-identity $r(a) \cdot s(a) = \mathbf{S}(r)(s)(a)$ already quoted; $\mathbf{G}$ appears as the constant map $\mathbf{K}(\mathbf{G})$ applied to a. The element a itself is recovered as $\mathbf{I}(a)$ with $\mathbf{I}$ combinatory. ■

Theorem (`theorem_3_6.finite`). If $a = \mathbf{cond}(\langle a'_0, \ldots\rangle)(\mathbf{G})$ is the single generator of a finite list, then the packed sequence $\langle a'_0, \ldots\rangle$ and the generator $\mathbf{G}$ both lie in $\mathbf{Deg}(a)$.

Proof. The packed sequence equals $a(0)$, and 0 is r.e., so evaluation at 0 is an r.e. operation applied to a. The generator $\mathbf{G}$ belongs to every degree by the preceding theorem. ■

Theorem (`theorem_3_6.converse`). Every x belongs to $\mathbf{Deg}(\mathbf{cond}(\langle x\rangle)(\mathbf{G}))$.

Proof. By the finite-list lemma, the singleton packing $\langle x\rangle$ lies in that degree. Applying it to 0 (again an r.e. operation, and degrees are closed under application) recovers x. ■

3.4.15 Theorem 3.7 ✓

Among the subsets of $\mathbf{P}\omega$ with natural mathematical structure, we of course have $\mathbf{FUN}$, which is a semigroup under $\circ = \lambda u \lambda v \lambda x.\, u(v(x))$. It is, however, a rather complicated semigroup. We introduce for its study three new combinators:

$$\mathbf{R} = \lambda x.\, \langle 0, x\rangle; \tag{3.13}$$

$$\mathbf{L} = \lambda x.\, x_1(x_2); \tag{3.14}$$

$$\bar{u} = \lambda x.\, x_0 \supset \langle 1, u, x_1\rangle,\ \overline{u(x_1)(x_2)}. \tag{3.15}$$

THEOREM 3.7 (The semigroup theorem). The countable semigroup $\mathbf{RE} \cap \mathbf{FUN}$ of computable enumeration operators is finitely generated by $\mathbf{R}$, $\mathbf{L}$ and $\bar{\mathbf{G}}$.

The proof rests on the verification of two equations which permit an application of Theorem 3.1:

$$\mathbf{L} \circ \bar{u} \circ \mathbf{R} = \lambda x.\, u(x) \tag{3.16}$$

$$\bar{u} \circ \bar{v} \circ \mathbf{R} = \overline{u(v)}. \tag{3.17}$$

Certainly the word problem for $\mathbf{RE} \cap \mathbf{FUN}$ is unsolvable, indeed, not even recursively enumerable. Can the semigroup be generated by *two* generators by the way?

Proof of Theorem 3.7. We first establish (3.16) and (3.17):

$$\begin{aligned}\mathbf{L} \circ \bar{u} \circ \mathbf{R} &= \lambda x.\, \mathbf{L}(\bar{u}(\langle 0, x\rangle)) \\ &= \lambda x.\, \mathbf{L}(\langle 1, u, x\rangle) \\ &= \lambda x.\, u(x).\end{aligned}$$

$$\begin{aligned}\bar{u} \circ \bar{v} \circ \mathbf{R} &= \lambda x.\, \bar{u}(\bar{v}(\langle 0, x\rangle)) \\ &= \lambda x.\, \bar{u}(\langle 1, v, x\rangle)\end{aligned}$$

$$= \lambda x.\, \overline{u(v)}(x)$$
$$= \overline{u(v)}.$$

Now starting with any $u \in \mathbf{RE}$, we write $u = \tau$, where τ is formed from $\mathbf{G}$ by application alone. By (3.17), we can write $\bar{u}$ in terms of $\bar{\mathbf{G}}$ and $\mathbf{R}$ using only $\circ$. That is, $\bar{u}$ belongs to a special subsemigroup. In view of (3.16), we find that $\lambda x.\, u(x)$ belongs to that generated by $\mathbf{R}$, $\mathbf{L}$ and $\bar{\mathbf{G}}$. But

$$\mathbf{RE} \cap \mathbf{FUN} = \{\lambda x.\, u(x) \mid u \in \mathbf{RE}\},$$

and so the theorem is proved.

Formalization. Write $\circ$ for composition of enumeration operators. Say an element is *semigroup-generated* when it lies in the least class containing $\mathbf{R}$, $\mathbf{L}$ and $\bar{\mathbf{G}}$ and closed under $\circ$. Scott's claim is that this class coincides with $\mathbf{RE} \cap \mathbf{FUN}$.

Theorem (`theorem_3_7.equations`). For all u, v, x,

$$\mathbf{L}(\bar{u}(\mathbf{R}(x))) = u(x),$$

and writing $\langle 1, v, x\rangle$ for the positive branch of $\bar{v}$ at $\mathbf{R}(x)$,

$$\langle 1, v, x\rangle_1 = v, \qquad \langle 1, v, x\rangle_2 = x.$$

Proof. The first identity is (3.16) after evaluating $\bar{u}$ at $\mathbf{R}(x) = \langle 0, x\rangle$, which takes the positive branch $\langle 1, u, x\rangle$; $\mathbf{L}$ then applies the first component to the second. The two projection equations are the components of that same coded triple, as used in the calculation of (3.17). ■

Theorem (`theorem_3_7.generation`). If $u \in \mathbf{RE} \cap \mathbf{FUN}$, then u is semigroup-generated.

Proof. By Theorem 3.1, u is obtained from $\mathbf{G}$ by application alone, so $\bar{u}$ is obtained from $\bar{\mathbf{G}}$ and $\mathbf{R}$ by composition, using (3.17) inductively. Then $\mathbf{L} \circ \bar{u} \circ \mathbf{R}$ is semigroup-generated, and (3.16) identifies that composite with the graph $\lambda x.\, u(x)$. Since $u \in \mathbf{FUN}$, this graph is u itself. ■

Theorem (`theorem_3_7`). $u \in \mathbf{RE} \cap \mathbf{FUN}$ if and only if u is semigroup-generated.

Proof. One direction is the preceding generation lemma. Conversely, each of $\mathbf{R}$, $\mathbf{L}$ and $\bar{\mathbf{G}}$ is r.e. and functional, and $\mathbf{RE} \cap \mathbf{FUN}$ is closed under composition, so every semigroup-generated element lies in the intersection. ■

3.5 Retracts and data types

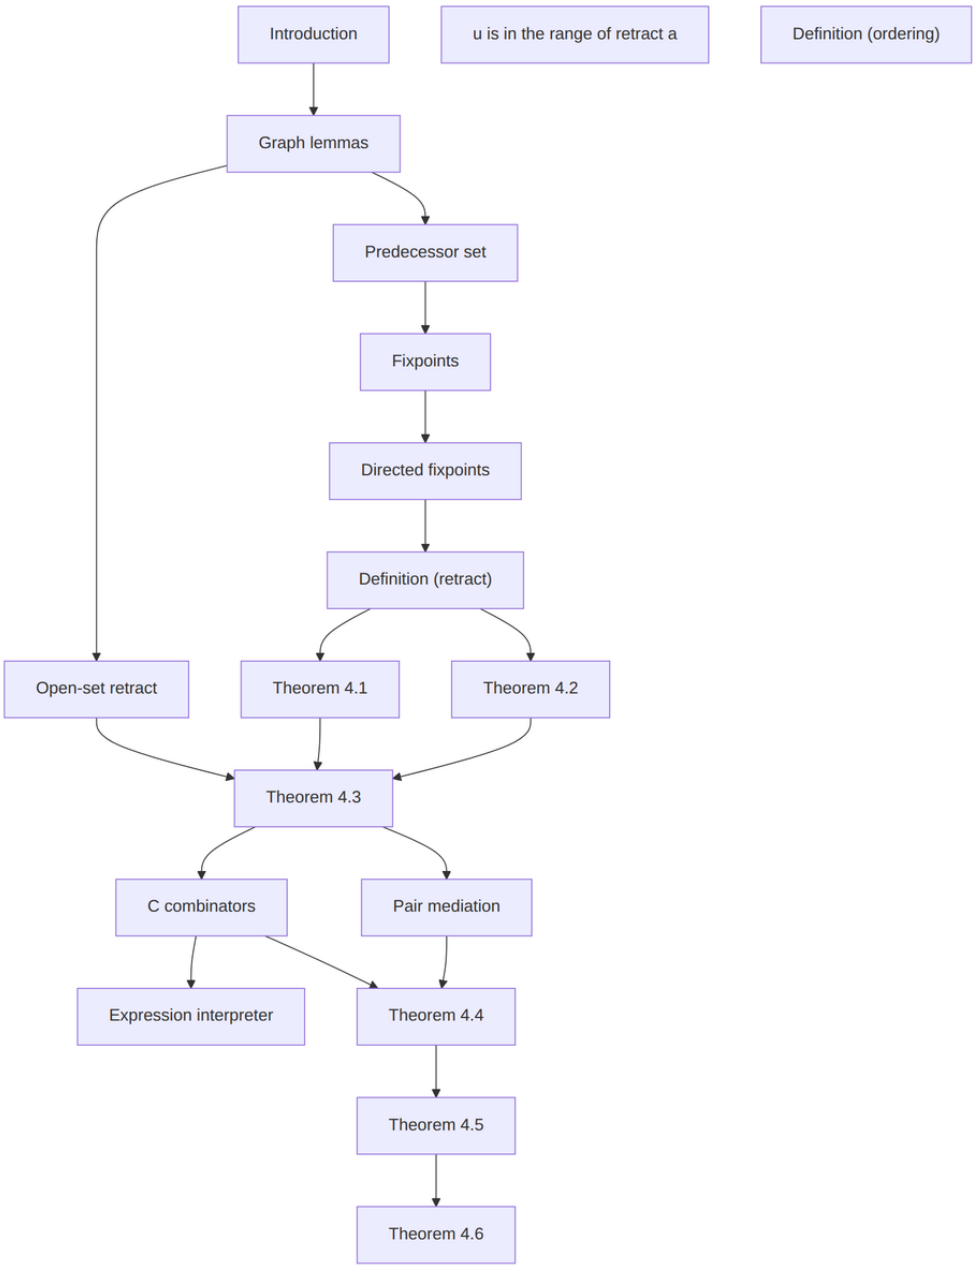

Figure 32: Retracts and data types.

3.5.1 Introduction ✓

Historical note. A retract is an ordinary notion of topology. The use of computable retracts as data types, the operations on those retracts, and the recursive definitions by fixed-point equations are Scott's. A continuous lattice, in the sense of [19], has continuous meet and join, and as a space it is a T_0-space satisfying the

extension theorem. The connection between lattices and fixed points was already known. The set of all retracts is a complete lattice by Theorem 4.1, and it is not itself a continuous lattice. Ershov solved that question after the body of the paper was written; [24] found essentially the same argument independently. The argument is given with the ordering of retracts. The correspondence was Scott's introduction to Ershov's numeration theory. Applications to the semantics of flow diagrams are in [25], and were taken up by [26] and by [27].

Data can be structured in many ways: ordered tuples, lists, arrays, trees, streams, and even operations and functions. The last point becomes clear if one thinks of *parameters*. We would normally hardly consider the pairing function $\lambda x \lambda y.\, \langle x, y \rangle$ as being in itself a piece of data. But if we treat the first variable as a *parameter*, then it can be specialized to a *fixed value*, say the element a, producing the function $\lambda y.\, \langle a, y \rangle$. This function is more likely to be the output of some process and *in itself* can be considered as a datum. It is rather like one *whole row* of a matrix. If we were to regard a two-argument function f as being a matrix, then its ath row would be exactly $\lambda y.\, f(a)(y)$. If s were a selection function, then, for example, $\lambda y.\, f(s(y))(y)$ would represent the selection of one element out of each column of the matrix. This selection could be taken as a specialization of parameters in the operator $\lambda u \lambda v \lambda y.\, u(v(y))(y)$. We have not been very definite here about the exact nature of the fixed a, f, or s, or the range of the variable y or the range of values of the function f. The point is only to recall a few elements of structure and to suggest an abstract view of data going beyond the usual iterated arrays and trees.

What then is a *data type*? Answer: a type of data. That is to say, a collection of data that have been grouped together for reasons of similarity of structure or perhaps mere convenience. Thus the collection may very well be a mixed bag, but more often than not canons of taste or demands of simplicity dictate an adherence to regularity. The grouping may be formed to eliminate irrelevant objects and focus the attention in other ways. It is frequently a matter of good organization that aids the understanding of complex definitions. In programming languages, one of the major reasons for making an explicit declaration of a data type (that is, the restriction of certain variables to certain *"modes"*) is that the computed objects of that type can enjoy a special *representation* in the machine that allows the manipulation of these objects via the chosen representation to be reasonably efficient. This is a very critical matter for good language design and good compiler writing. In this report, however, we cannot discuss the problems of representation,

important as they may be. Our objective here is conceptual organization, and we wish to show how such ideas, in the language for computable functions used here, can find the proper expression.

Which are the data types that can be defined in LAMBDA? No final answer can be given since the number is infinite and inexhaustible. From one point of view, however, there is only one: $\mathbf{P}\omega$ itself. It is the universal type and all other types are subtypes of it; so $\mathbf{P}\omega$ plays a primary role in this exposition. But in a way it is too big, or at least too complex, since each of its elements can be used in so many different ways. When we specify a subtype the intention is to restrict attention to a special use. But even the various subtypes overlap, and so the same elements still get different uses. Style in writing definitions will usually make the differentiation clear though. The main innovation to be described in this section is the use of LAMBDA expressions to define types *as well as* elements. Certain expressions define *retracts* (or better: retraction mappings), and it is the *ranges* (or as we shall see: *sets of finite points*) of such retracts that form the groupings into types. Thus LAMBDA provides a calculus of type definitions including *recursive* type definitions. Examples will be explained both here and in the following sections. Note that types as retracts turn out to be types as *lattices*, that is, types of partial and many-valued objects. The problem of cutting these lattice types down to the perfect or complete objects is discussed in § 6. Another view of types and functionality of mappings is presented in § 7.

The notion of a retract comes from (analytic) topology, but it seems almost an accident that the idea can

be applied in the present context. The word is employed not because there is some deep tie-up with topology but because it is short and rather descriptive. Three easy examples will motivate the general plan:

3.5.2 Graph lemmas ✓

Two elementary graph identities used throughout the retract constructions.

Theorem (`graph_ext`). If $f(x) = g(x)$ for all x, then $\mathrm{graph}(f) = \mathrm{graph}(g)$.

Proof. Unfold the graph coding; the pointwise equality rewrites the defining set. ■

Theorem (`graph_const_bot`). The graph of the constant map with value $\bot$ is $\bot$.

Proof. No coded pair lies in the empty set. ■

`graphLemmas.lean`

    graph f = graph g := by
  simp [graph, h]

theorem graph_const_bot : graph (fun _ => botElem) = botElem := by
  ext p
  simp [graph, botElem]

end DomainTheory.DataTypesAsLattices
```

3.5.3 Predecessor set ✓

Predecessor-set identities for numerals, used when building integer retracts.

Theorem (`predSet_ofNat_zero`). $\mathrm{predSet}(0) = \bot$.

Proof. The predecessor of the singleton $\{0\}$ is empty. ■

Theorem (`predSet_eq_ofNat_of_no_zero`). If $0 \notin u$ and $\mathrm{predSet}(u) = k$, then $u = k + 1$ as numerals.

Proof. Members of u are successors; the predecessor condition forces each to be exactly $k + 1$, and conversely $k + 1$ has predecessor k. ■

3.5.4 Fixpoints ✓

The fixed-point set of a continuous self-map of $\mathbf{P}\omega$ is the carrier of Theorem 4.1.

Definition (`Fixpoints`). $\mathrm{Fixpoints}(f) = \{x \mid f(x) = x\}$.

Definition (`Fixpoints.vals`). For a set A of fixed points (as a subtype), $\mathrm{vals}(A)$ is the underlying set of elements of $\mathbf{P}\omega$.

Theorem (`Fixpoints.vals.subset`). $\mathrm{vals}(A) \subseteq \mathrm{Fixpoints}(f)$.

Proof. Each element of $\mathrm{vals}(A)$ is the underlying point of some fixed-point witness. ■

`Fixpoints.lean`

end DomainTheory.DataTypesAsLattices
```

Directed compact fixed points ✓ Directed families of fixed points of a continuous self-map of $\mathbf{P}\omega$, and the compactness property used for continuous retract lattices.

Definition (`DirectedSubset`). A nonempty set s of fixed points of f is directed when any two members have an upper bound in s under $\subseteq$.

Definition (`IsCompactSubset`). A fixed point x is compact (relative to f) when every directed family of fixed points whose union covers x has a single member that already covers x.

Theorem (`directed_finite_cover`). If A is a directed set of fixed points and $t \subseteq \mathbf{P}\omega$ is finite and contained in $\bigcup \mathrm{vals}(A)$, then some $z \in A$ already contains t.

Proof. Induct on the finite set: the empty set is covered by any member of the nonempty directed family; for an inserted point, take upper bounds for the inductive cover and for a witness covering the new point. ■

3.5.6 Definition (retract) ✓

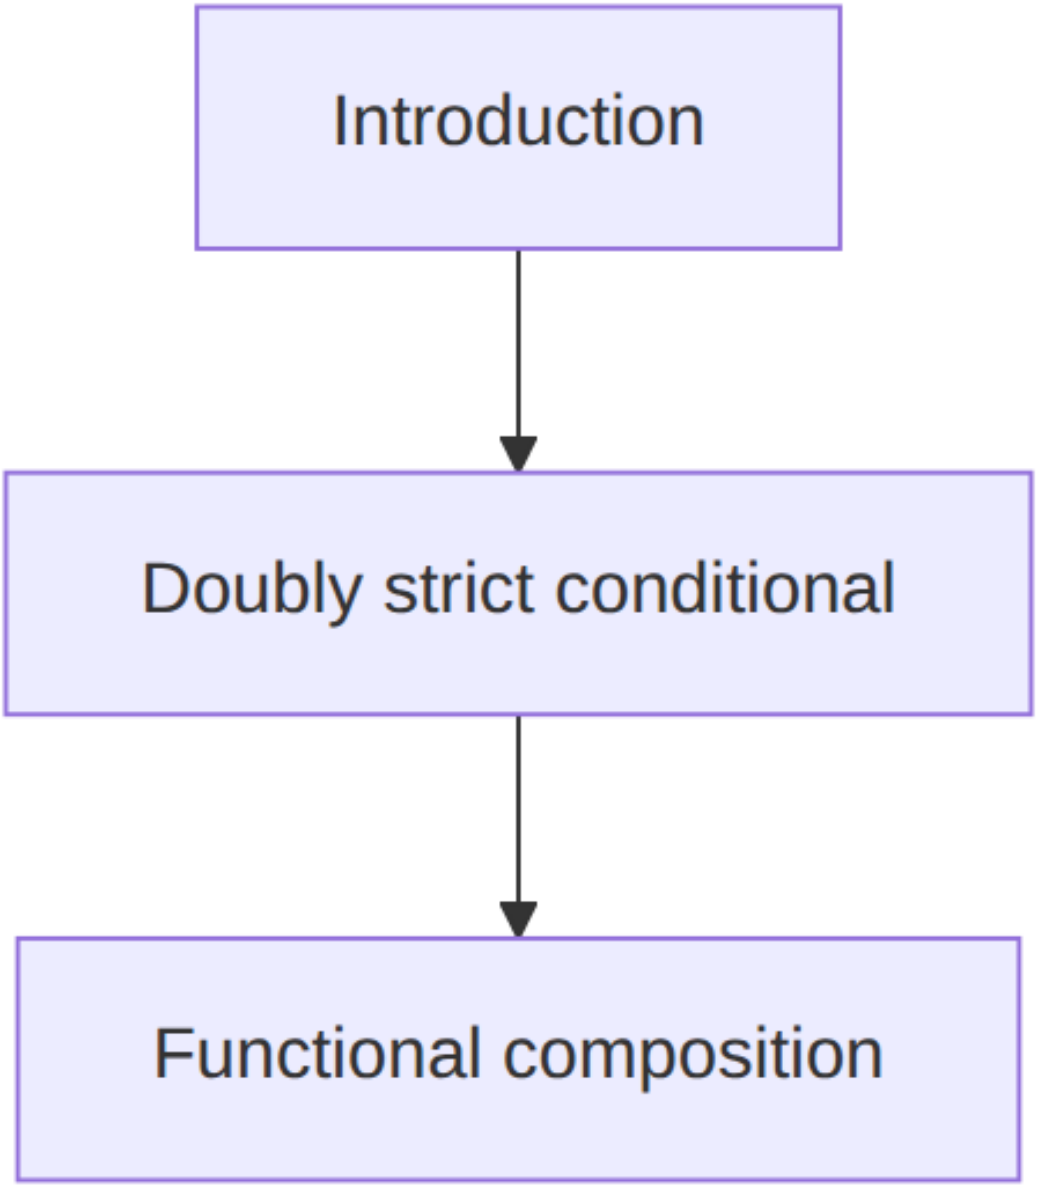

Figure 34: Definition (retract) ✓.

Introduction ✓ **DEFINITION.** An element $a \in \mathbf{P}\omega$ is called a *retract* iff it satisfies the equation $a = a \circ a$.

Of course the $\circ$-notation is used for functional composition in the standard way:

$$(4.5)\quad u \circ v = \lambda x.\, u(v(x)).$$

Consider these combinators:

$$(4.1)\quad \mathbf{fun} = \lambda u \lambda x.\, u(x);$$

$$(4.2)\quad \mathbf{pair} = \lambda u.\, \langle u_0, u_1 \rangle;$$

$$(4.3)\quad \mathbf{bool} = \lambda u.\, u \sqsupset 0, 1.$$

Here $\sqsupset$ is the *doubly strict conditional* defined by

$$(4.4)\quad z \sqsupset x, y = z \supset (z \supset x, \top), (z \supset \top, y),$$

which has the property that if z is both zero and positive, then it takes the value $\top$ instead of the value $x \cup y$.

It is quite simple to prove that each of the three combinators in (4.1)–(4.3) is a retract according to the definition. But what is the point?

Consider $\mathbf{fun}$. No matter what $u \in \mathbf{P}\omega$ we take, $\mathbf{fun}(u)$ is (the graph of) a *function*. And if u already is (the graph of) a function, then $u = \mathbf{fun}(u)$. That is to say, the range of $\mathbf{fun}$ is the same as the set of fixed points of $\mathbf{fun}$ is the same as the set of all (graphs of) functions. Any mapping a whose range and fixed-point set

coincide satisfies $a = a \circ a$, and conversely. A retract is a mapping which "retracts" the whole space onto its range and which is the identity mapping on its range. That is the import of the equation $a = a \circ a$. Strictly speaking, the range is the retract and the mapping is the retraction, but for us the mapping is more important. (Note, however, that distinct retracts can have the same range.) We let the mapping stand in for the range.

Thus the combinator **fun** represents in itself the concept of a *function* (continuous function on $\mathbf{P}\omega$ into $\mathbf{P}\omega$). Similarly **pair** represents the idea of a *pair* and **bool** the idea of being a boolean value as an element of $\{\bot, 0, 1, \top\}$, since we must think in the multiple-valued mode. What is curious (and, as we shall see, useful) is that all these retracts which are defining subspaces are at the same time elements of $\mathbf{P}\omega$.

Doubly strict conditional ✓ The doubly strict conditional of (4.4), used to define $\mathbf{bool}$.

Definition (`dcondSet`). For $z, x, y \in \mathbf{P}\omega$,

$$z \sqsupset x, y \;=\; z \supset \big(z \supset x,\, \top\big),\; \big(z \supset \top,\, y\big).$$

Equivalently, nest McCarthy's conditional: test z for zero, and on each branch test z again against $\top$ so that a mixed tag (both zero and positive) yields $\top$ instead of $x \cup y$.

Theorem (`dcondSet.isScottContinuous_left`). For fixed x, y, the map $z \mapsto z \sqsupset x, y$ is Scott-continuous.

Proof. Composition of continuous McCarthy conditionals (in each argument) with the continuous identity and the continuous maps $z \mapsto z \supset x, \top$ and $z \mapsto z \supset \top, y$. ■

Theorem (`dcondSet.isScottContinuous_mid`). For fixed z, y, the map $x \mapsto z \sqsupset x, y$ is Scott-continuous.

Proof. As a composite of continuous conditionals in the middle argument. ■

Theorem (`dcondSet.isScottContinuous_right`). For fixed z, x, the map $y \mapsto z \sqsupset x, y$ is Scott-continuous.

Proof. As a composite of continuous conditionals in the right argument. ■

Theorem (`dcondSet.bot`). $\bot \sqsupset x, y = \bot$.

Proof. Both nested conditionals see an empty tag, so the result is empty. ■

Theorem (`dcondSet.cases`). For any z, exactly one of the following holds: z is a pure zero tag ($0 \in z$ and no positive); a pure positive tag ($0 \notin z$ and some $k{+}1 \in z$); mixed (both); or empty (neither).

Proof. Case-split on membership of 0 and of some successor. ■

Theorem (`dcondSet.of_empty`). If z is empty (neither zero nor positive), then $z \sqsupset x, y = \bot$.

Proof. Neither branch of the outer conditional can fire. ■

Theorem (`dcondSet.of_zero_not_pos`). If z is a pure zero tag, then $z \sqsupset x, y = x$.

Proof. The outer test takes the "zero" branch; the inner $z \supset x, \top$ collapses to x, while the unused right branch is $\top$. ■

Theorem (`dcondSet.of_pos_not_zero`). If z is a pure positive tag, then $z \sqsupset x, y = y$.

Proof. Symmetrically: the outer test takes the "positive" branch, and $z \supset \top, y$ collapses to y. ■

Theorem (`dcondSet.of_mixed`). If z is mixed, then $z \sqsupset x, y = \top$.

Proof. Both inner conditionals evaluate to $\top$ (each has a live tag forcing the $\top$ arm), so the outer conditional yields $\top$. ■

Theorem (`dcondSet.ofNat_zero`). $0 \sqsupset x, y = x$.

Proof. The numeral 0 is a pure zero tag. ■

Theorem (`dcondSet.ofNat_one`). $1 \sqsupset x, y = y$.

Proof. The numeral 1 is a pure positive tag. ■

Theorem (`dcondSet.ofNat_succ`). For every n, $(n{+}1) \sqsupset x, y = y$.

Proof. Every positive numeral is a pure positive tag. ■

Theorem (`dcondSet.top`). $\top \sqsupset x, y = \top$.

Proof. $\top$ is mixed (contains 0 and every successor). ■

Theorem (`dcondSet.bool_idem`). $(u \sqsupset 0, 1) \sqsupset 0, 1 \;=\; u \sqsupset 0, 1$.

Proof. By the four cases on u: pure zero gives $0 \sqsupset 0, 1 = 0$; pure positive gives $1 \sqsupset 0, 1 = 1$; mixed gives $\top \sqsupset 0, 1 = \top$; empty gives $\bot \sqsupset 0, 1 = \bot$. In each case a second $\sqsupset 0, 1$ is the identity on that value. ■

Functional composition ✓ Functional composition (4.5), the retract equation, and the motivating combinators **fun** and **bool**.

Definition (`comp`). Composition of graphs is

$$u \circ v \;=\; \mathbf{graph}\big(x \mapsto u(v(x))\big),$$

Scott's equation (4.5).

Theorem (`comp.app`). $(u \circ v)(x) = u(v(x))$.

Proof. The body $x \mapsto u(v(x))$ is Scott-continuous (composite of continuous applications), so (β) applies. ■

Theorem (`comp.isScottContinuous_right`). For fixed u, the map $v \mapsto u \circ v$ is Scott-continuous.

Proof. The graphing of a family continuous in v (pointwise $x \mapsto u(v(x))$ is continuous in v) is continuous. ■

Theorem (`comp.right_const`). For fixed a, the map $u \mapsto u \circ a$ is Scott-continuous.

Proof. Likewise: $x \mapsto u(a(x))$ is continuous in u, and graphing preserves that. ■

Definition (`Retract`). An element $a \in \mathbf{P}\omega$ is a *retract* when $a = a \circ a$.

Definition (`funRetract`). Scott's **fun** of (4.1):

$$\mathbf{fun} = \mathbf{graph}\big(u \mapsto \mathbf{graph}(x \mapsto u(x))\big).$$

Theorem (`funRetract.app`). $\mathbf{fun}(u) = \mathbf{graph}(x \mapsto u(x))$.

Proof. (β): the body is continuous in u because application is continuous in the function argument. ■

Theorem (`funRetract.isRetract`). **fun** is a retract: $\mathbf{fun} = \mathbf{fun} \circ \mathbf{fun}$.

Proof. Pointwise on graphs: for each u, $\mathbf{fun}(\mathbf{fun}(u)) = \mathbf{graph}(x \mapsto \mathbf{fun}(u)(x)) = \mathbf{graph}(x \mapsto u(x)) = \mathbf{fun}(u)$, using (β) for continuous u. ■

Definition (`boolR`). Scott's **bool** of (4.3):

$$\mathbf{bool} = \mathbf{graph}\big(u \mapsto u \sqsupset 0, 1\big).$$

Theorem (`boolR.app`). $\mathbf{bool}(u) = u \sqsupset 0, 1$.

Proof. (β) from continuity of $u \mapsto u \sqsupset 0, 1$ in the left argument of $\sqsupset$. ■

Theorem (`boolR.isRetract`). **bool** is a retract: $\mathbf{bool} = \mathbf{bool} \circ \mathbf{bool}$.

Proof. Pointwise: $\mathbf{bool}(\mathbf{bool}(u)) = (u \sqsupset 0, 1) \sqsupset 0, 1 = u \sqsupset 0, 1 = \mathbf{bool}(u)$ by idempotence of $\sqsupset 0, 1$. ■

(Scott's **pair** of (4.2) is not yet a named retract module; pairing of elements is `pairSeq` elsewhere.)

3.5.7 Theorem 4.1 ✓

For Section 4. The notion of a *continuous lattice* is due to [28, 29] and we shall not review all the facts here. One special feature of these lattices is that the lattice operations of meet and join ($\sqcap$ and $\sqcup$) are continuous (that is, commute with directed sups). As topological spaces, they can be characterized as those T_0-spaces satisfying the extension theorem (which we proved for $\mathbf{P}\omega$ in Theorem 1.5).

THEOREM 4.1 (The lattice theorem). The fixed points of any continuous function form a complete lattice (under $\subseteq$); while those of a retract form a continuous lattice.

Proof of Theorem 4.1. Consider a continuous function a, and let $A = \{x \mid x = a(x)\}$. By the fixed-point theorem (Theorem 1.4) we know that A is nonempty and that it has a least element under $\subseteq$. Certainly A is partially ordered by $\subseteq$; further, A is closed under *directed* unions but not under arbitrary unions.

That is, A is not a complete sublattice of $\mathbf{P}\omega$ with regard to the lattice operations of $\mathbf{P}\omega$, but it could be a complete lattice on its own—if we can show sups exist. Thus, let $S \subseteq A$ be an arbitrary subset of A. By the fixed-point theorem, find the least solution to the equation:

$$y = \bigcup\{x \mid x \in S\} \cup a(y).$$

Clearly $x \subseteq y$ for all $x \in S$; and so $x = a(x) \subseteq a(y)$, for all $x \in S$. This means that $y = a(y)$, and thus $y \in A$. By construction, then, y is an upper bound to the elements of S. Suppose $z \in A$ is another upper bound for S. It will also satisfy the above equation; thus $y \subseteq z$, and so y is the least upper bound. A partially ordered set with sups also has infs, as is well known, and is a complete lattice.

Suppose that a is a retract. We can easily show that the fixed-point set A (with the relative topology from $\mathbf{P}\omega$) satisfies the extension theorem. For assume $f : X \to A$ is continuous, and $X \subseteq Y$ as a subspace. Now we can also regard $f : X \to \mathbf{P}\omega$ as continuous because A is a subspace of $\mathbf{P}\omega$. By Theorem 1.5 there is an extension to a continuous $\bar{f} : Y \to \mathbf{P}\omega$. But then $a \circ \bar{f} : Y \to A$ is the continuous function we want for A, and the proof is complete.

The space of retracts. Let us define:

$$\mathbf{RET} = \{a \mid a = a \circ a\},$$

the set of all retracts, which is a complete lattice in view of Theorem 4.1. It will be proved to be not a retract itself by showing it is not a continuous lattice; in fact, the meet operation on $\mathbf{RET}$ is not continuous on $\mathbf{RET}$.

The proof was kindly communicated by Y. L. Ershov and rests on distinguishing some extreme cases of retracts. Call a retract a *nonextensive* if for all nonempty finite sets x we have $x \not\subseteq a(x)$. Call a retract b *finite* if all its values are finite (i.e., $b(\top)$ is finite). If a is nonextensive and b is finite, then Ershov notes that

they are "orthogonal" in **RET** in the sense that $c = a \sqcap b = \bot$. The reason is that, since $c \subseteq b$, it is finite; but $c \subseteq a$, too, so $c(x) \subseteq a(x)$ for all x. Because c is a retract, we have $c(x) = c(c(x)) \subseteq a(c(x))$. As $c(x)$ is finite and a is nonextensive, it follows that $c(x) = \bot$ for all x.

This orthogonality is unfortunate, because consider the finite retracts $b_n = \lambda x.\, e_n$. We have here a directed set of retracts where $\bigcup\{b_n \mid n \in \omega\} = \lambda x.\, \top = \top$. If $\sqcap$ were continuous, it would follow that for nonextensive a:

$$a = a \sqcap \top = a \sqcap \bigcup\{b_n \mid n \in \omega\} = \bigcup\{a \sqcap b_n \mid n \in \omega\} = \bot,$$

showing that there are no nontrivial such a. But this is not so.

Let $\ll$ be a strict linear ordering of ω in the order type of the rational numbers. Define:

$$a(x) = \{m \mid \exists n \in x.\, m \ll n\}.$$

We see at once that a is continuous; and, because $\ll$ is transitive and dense, a is a retract. Since $\ll$ is irreflexive, it is the case for finite nonempty sets x that $\max_{\ll}(x) \notin a(x)$; hence, a is nonextensive. As $a(\top) = \top$, we find $a \neq \bot$. The proof is complete.

Note that there are many transitive, dense, irreflexive relations on ω, so there are many nonextensive retracts. These retracts, like a above, are *distributive*.

A nondistributive example is:

$$a' = \{m \mid \exists n, n' \in x.\, n \ll m \ll n'\}.$$

Many other examples are possible.

3.5.8 u is in the range of retract a ✓

DEFINITION. If a is a retract, we write $u : a$ for $u = a(u)$ and $\lambda u : a.\, \tau$ for $\lambda u.\, \tau[a(u)/u]$.

Since retracts are sets in $\mathbf{P}\omega$, we cannot use the ordinary membership symbol to signify that u belongs to the range of a; so we write $u : a$. The other notation with the λ-operator restricts a function to the range of a. For f to be so restricted simply means $f = f \circ a$. For the range of f to be contained in that of the retract a means $f = a \circ f$. These algebraic equations will be found to be quite handy. We are going to have a calculus of retracts and mappings between them involving many operators on retracts yet to be discovered. Before we turn to this calculus, we recall the well-known connection between lattices and fixed points.

3.5.9 Definition (ordering) ✓

We note further that by the embedding theorem (Theorem 1.6), it follows that any separable (by which we mean countably-based) continuous lattice is a retract of $\mathbf{P}\omega$; hence, our universal space is indeed rich in

retracts. A very odd point is that $a = a \circ a$ is a fixed-point equation itself ($\lambda u.\, u \circ u$ is obviously continuous). Thus the retraction mappings form a complete lattice. Is this a continuous lattice? (Ershov has proved it is not; see the Appendix for a sketch.) A related question is solved positively in the next section. Actually the ordering of retracts under $\subseteq$ does not seem to be all that interesting; a more algebraic ordering is given by:

DEFINITION. For retracts a and b we write $a \sqsubseteq b$ for $a = a \circ b = b \circ a$.

The idea here should be clear: $a \sqsubseteq b$ means that a is a retract of b. It is easy to prove the:

3.5.10 Open-set retract ✓

An open-set retract used later when comparing retracts and Scott-open structure.

Definition (`openSetRetract`). openSetRetract is the graph of the map sending u to $\{m \mid \exists n.\, e_n \subseteq e_m \wedge n \in u\}$: the Scott-open sets coded by members of u.

end DomainTheory.DataTypesAsLattices
```

3.5.11 Theorem 4.2 ✓

THEOREM 4.2 (The partial ordering theorem). The retracts are partially ordered by $\sqsubseteq$.

There do not seem to be any lattice properties of $\sqsubseteq$ of a general nature. Note, however, that if retracts commute, $a \circ b = b \circ a$, then $a \circ b$ is the greatest lower bound under $\sqsubseteq$ of a and b. Also if we have a sequence where both $a_n \sqsubseteq a_{n+1}$ and $a_n \subseteq a_{n+1}$ for all $n \in \omega$, then $\bigcup\{a_n \mid n \in \omega\}$ is the upper bound for the a_n under $\sqsubseteq$, as can easily be argued from the definition by continuity of $\circ$.

Certainly there is no "least" retract under $\sqsubseteq$. One has $\bot = \bot \circ a$ (recall: $\bot = \lambda x.\, \bot$), but not $a \circ \bot = \bot$. This last equation means more simply that $a(\bot) = \bot$; that is, a is *strict*. For retracts strictness is thus equivalent to $\bot \sqsubseteq a$, so we can say that there is a least strict retract. The combinator $\mathbf{I} = \lambda u.\, u$ clearly represents the

largest retract (the *whole space*), and it is strict also. In a certain sense strictness can be assumed without loss of generality. For if a is not strict, let

$$b = \lambda x.\, \{n \mid a(x) \neq a(\bot)\}.$$

This function takes values in $\{\bot, \top\}$ and is continuous because $\{x \in \mathbf{P}\omega \mid a(x) \neq a(\bot)\}$ is *open*. Next define:

$$a^* = \lambda u.\, a(u) \cap b(u).$$

This is a strict retract whose range is homeomorphic (and lattice isomorphic) to that of a. Note, however, that the mapping from a to a^* is not continuous (or even monotonic).

To have a more uniform notation for retracts we shall often write **nil**, **id**, and **seq** for the combinators $\bot$, **I**, \$. Two further retracts of interest are

$$(4.6) \quad \mathbf{open} = \lambda u.\, \{m \mid \exists e_n \subseteq e_m.\, n \in u\};$$

$$(4.7) \quad \mathbf{int} = \lambda u.\, u \supset 0,\, \mathbf{int}(u-1) \supset u,\, u.$$

The range of **open** is lattice isomorphic to the lattice of open subsets of $\mathbf{P}\omega$; definition (4.6) is not a LAMBDA-definition of the retract, but such can be given.

In (4.7) we intend **int** to be the least fixed point of the equation. By induction on the least element of u (if any) one proves that:

$$\mathbf{int}(u) = \begin{cases} \bot & \text{if } u = \bot; \\ u & \text{if } u \in \omega; \\ \top & \text{otherwise.} \end{cases}$$

This retract wipes out the distinctions between multiple values, moving all above the singletons up to $\top$; its range thus has a very simple structure. The retract **int** clearly generalizes **bool**. The range of **fun** is homeomorphic to the space of all continuous functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$; the range of **pair**, to the space of all ordered pairs; the range of **seq**, to the space of all infinite sequences. A combination like $\lambda u.\, \mathbf{int} \circ \mathbf{seq}(u)$ is a retract whose range is homeomorphic to the space of infinite sequences of elements from the range of **int**.

We now wish to introduce some operators that provide systematic ways of forming new combinations of retracts. There are three principal ones:

$$(4.8) \quad a\circ \to b = \lambda u.\, b \circ u \circ a;$$

$$(4.9) \quad a \otimes b = \lambda u.\, \langle a(u_0), b(u_1)\rangle;$$

$$(4.10) \quad a \oplus b = \lambda u.\, u_0 \supset \langle 0, a(u_1)\rangle,\, \langle 1, b(u_1)\rangle.$$

These equations clearly generalize (4.1)–(4.3). Before we explain our operators, note these three equations which hold for arbitrary a, b, a', b':

$$(4.11) \quad (a\circ \to b) \circ (a'\circ \to b') = (a' \circ a)\circ \to (b \circ b');$$

$$(4.12) \quad (a \otimes b) \circ (a' \otimes b') = (a \circ a') \otimes (b \circ b');$$

$$(4.13) \quad (a \oplus b) \circ (a' \oplus b') = (a \circ a') \oplus (b \circ b').$$

The reversal of order $(a' \circ a)$ on the right-hand side of (4.11) should be remarked.

These equations will be used not only for properties of types (ranges of retracts) but also for the mappings between the types.

Proof of Theorem 4.2. The relation $\sqsubseteq$ is by the definition of retract reflexive on $\mathbf{RET}$; it is also obviously antisymmetric. To prove transitivity, suppose $a \sqsubseteq b \sqsubseteq c$, then

$$a = a \circ b = a \circ b \circ c = a \circ c.$$

Similarly, $a = c \circ a$. Note, by the way, that $a \sqsubseteq b$ implies that the range of a is included in that of b; but that the relationship $a \subseteq b$ does not imply this fact. The relationship $a \sqsubseteq b$, however, is stronger than inclusion of ranges.

3.5.12 Theorem 4.3 ✓

THEOREM 4.3 (The function space theorem). Suppose a, b, a', b', c are retracts. Then we have:

(i) $a\circ \to b$ is a retract, and it is strict if b is;

(ii) $u : a\circ \to b$ iff $u = \lambda x : a.\, u(x)$ and $\forall x : a.\, u(x) : b$;

(iii) if $a \sqsubseteq a'$ and $b \sqsubseteq b'$, then $a\circ \to b \sqsubseteq a'\circ \to b'$;

(iv) if $f : a\circ \to b$ and $f' : a'\circ \to b'$, then $f\circ \to f' : (b\circ \to a')\circ \to (a\circ \to b')$;

(v) if $f : a\circ \to b$ and $f' : b\circ \to c$, then $f' \circ f : a\circ \to c$.

Parts (i), (iii), (iv), and (v) can be proved using (4.8) and (4.11) in an algebraic (formal) fashion. It is (ii) that tells us what it all means: the range of $a\circ \to b$ consists exactly of those functions which are restricted to (the range of) a and which have values in b. So we can read $u : a\circ \to b$ in the normal way: u is a (continuous) mapping from a into b. In technical jargon, we can say that the (strict) retracts and continuous functions form a *category*. In fact, it is equivalent to the category of separable continuous lattices and continuous maps. In this context, (iv) shows that $\circ \to$ operates not only on spaces (retracts) but also on

maps: it is a functor contravariant in the first argument and covariant in the second. Further categorical properties will emerge.

Proofs of Theorems 4.3–4.5. We will not give full details as all the parts of these theorems are direct calculations. Consider by way of example Theorem 4.3(i). We find:

$$\begin{aligned}(a\circ\to b)\circ(a\circ\to b) &= \lambda u.\, b\circ(b\circ u\circ a)\circ a\\ &= \lambda u.\, b\circ u\circ a\\ &= a\circ\to b,\end{aligned}$$

provided that a and b are retracts. A very similar computation would verify part (iv), if one writes out the composition:

$$(a\circ\to b')\circ(f\circ\to f')\circ(b\circ\to a')$$

and uses the equations:

$$f = b\circ f\circ a \quad\text{and}\quad f' = b'\circ f'\circ a'.$$

3.5.13 C combinators ✓

Sum and product combinators for retracts: tag tests, injections, diagonal, curry, and evaluation.

Definition (`whichC`). $\mathrm{whichC} = \mathrm{fstC}$.

Theorem (`whichC.app`). $\mathrm{whichC}\,u = u(0)$.

Proof. The first-projection law. ■

Definition (`outC`). $\mathrm{outC} = \mathrm{sndC}$.

Definition (`outleftC`). $\mathrm{outleftC}$ is the graph of $u \mapsto \mathrm{cond}(u(0),\, u(1),\, \bot)$.

Theorem (`outleftC.isScottContinuous`). That body map is Scott-continuous.

Proof. Continuity of the conditional in its first two arguments along continuous projections. ■

Theorem (`outleftC.app`). Applying $\mathrm{outleftC}$ recovers the conditional body.

Proof. The β-law for the continuous body. ■

Definition (`outrightC`). $\mathrm{outrightC}$ is the graph of $u \mapsto \mathrm{cond}(u(0),\, \bot,\, u(1))$.

Theorem (`outrightC.isScottContinuous`). That body map is Scott-continuous.

Proof. Continuity of the conditional in its first and third arguments along continuous projections. ■

Theorem (`outrightC.app`). Applying $\mathrm{outrightC}$ recovers the conditional body.

Proof. The β-law for the continuous body. ■

Definition (`inrightC`). $\mathrm{inrightC}$ is the graph of $x \mapsto \langle 1, x\rangle$.

Theorem (`inrightC_app`). $\mathrm{inrightC}\,x = \langle 1, x\rangle$.

Proof. The β-law for continuous right pairing at tag 1. ■

Definition (`inleftC`). $\mathrm{inleftC}$ is the graph of $x \mapsto \langle 0, x\rangle$.

Theorem (`inleftC.app`). $\mathrm{inleftC}\,x = \langle 0, x\rangle$.

Proof. The β-law for continuous right pairing at tag 0. ■

Theorem (`curryC_isScottContinuous`). The map $u \mapsto \mathrm{graph}\big(x \mapsto \mathrm{graph}(y \mapsto u(\langle x, y\rangle))\big)$ is Scott-continuous.

Proof. Nested graph-constant continuity using left-continuity of application at a paired argument. ■

Theorem (`curryC_app`). $\mathrm{curryC}\,u = \mathrm{graph}\big(x \mapsto \mathrm{graph}(y \mapsto u(\langle x, y\rangle))\big)$.

Proof. The β-law for that continuous outer map. ■

Theorem (`curry_mid_isScottContinuous`). For fixed u, the mid map $x \mapsto \mathrm{graph}(y \mapsto u(\langle x, y\rangle))$ is Scott-continuous.

Proof. Graph-constant continuity from continuous application of u along continuous left pairing. ■

Theorem (`diagC_app`). $\mathrm{diagC}\,u = \langle u, u\rangle$.

Proof. The β-law for the continuous diagonal of pairing. ■

Theorem (`evalC_isScottContinuous`). The map $u \mapsto u(0)\,(u(1))$ is Scott-continuous.

Proof. Continuity of application in both arguments along the two projections. ■

Theorem (`evalC_app`). $\mathrm{evalC}\,u = u(0)\,(u(1))$.

Proof. The β-law for that continuous body. ■

3.5.14 Pair mediation ✓

The mediating arrow into a tensor product of retracts.

Definition (`pairMed`). For maps f, g and a retract c,

$$\mathrm{pairMed}(f, g, c) = (f \otimes g) \circ \mathrm{diagC} \circ c.$$

That is the composite of c with the diagonal into $c \otimes c$, then the tensor of f and g.

  comp (tensorR f g) (comp diagC c)

end DomainTheory.DataTypesAsLattices
```

3.5.15 Theorem 4.4 ✓

THEOREM 4.4 (The product theorem). Suppose a, b, a', b' are retracts. Then we have:

(i) $a \otimes b$ is a retract, and it is strict if a and b are;

(ii) $u : a \otimes b$ iff $u = (u_0, u_1)$ and $u_0 : a$ and $u_1 : b$;

(iii) if $a \sqsubseteq a'$ and $b \sqsubseteq b'$, then $a \otimes b \sqsubseteq a' \otimes b'$;

(iv) if $f : a\circ \to b$ and $f' : a'\circ \to b'$, then $f \otimes f' : a \otimes a'\circ \to b \otimes b'$.

Again the operator proves to be a functor, but what is stated in Theorem 4.4 is not quite enough for the standard identification of $\otimes$ as the categorical product. For this we need some additional combinators:

$$\mathbf{fst} = \lambda u.\, u_0; \tag{4.14}$$

$$\mathbf{snd} = \lambda u.\, u_1; \tag{4.15}$$

$$\mathbf{diag} = \lambda u.\, \langle u, u \rangle. \tag{4.16}$$

Then we have these properties:

$$(4.17) \quad \mathbf{fst} \circ (a \otimes b) : (a \otimes b)\circ \to a;$$

$$(4.18) \quad \mathbf{snd} \circ (a \otimes b) : (a \otimes b)\circ \to b;$$

$$(4.19) \quad \mathbf{diag} \circ a : a\circ \to a \otimes a;$$

$$(4.20) \quad \mathbf{fst} \circ (f \otimes f') = f \circ \mathbf{fst};$$

$$(4.21) \quad \mathbf{snd} \circ (f \otimes f') = f' \circ \mathbf{snd}.$$

Here a and b are retracts and f and f' are functions. Now suppose a, b, and c are retracts and $f : c\circ \to a$ and $g : c\circ \to b$. Let

$$h = (f \otimes g) \circ \mathbf{diag} \circ c.$$

We can readily prove that:

$$h : c\circ \to (a \otimes b),$$

and

$$\mathbf{fst} \circ h = f \quad \text{and} \quad \mathbf{snd} \circ h = g.$$

Furthermore, h is the *unique* such function. It is this uniqueness and existence property of functions into $a \otimes b$ that identifies the construct as a product.

There are important connections between $\circ \to$ and $\otimes$. To state these we require some additional combinators:

$$(4.22) \quad \mathbf{eval} = \lambda u.\, u_0(u_1);$$

$$(4.23) \quad \mathbf{curry} = \lambda u \lambda x \lambda y.\, u(\langle x, y\rangle).$$

If a, b, and c are retracts, the mapping properties are:

$$(4.24) \quad \mathbf{eval} \circ ((b\circ \to c) \otimes b) : ((b\circ \to c) \otimes b)\circ \to c;$$

$$(4.25) \quad \mathbf{curry} \circ ((a \otimes b)\circ \to c) : ((a \otimes b)\circ \to c)\circ \to (a\circ \to (b\circ \to c)).$$

Suppose next that $f : (a \otimes b)\circ \to c$ and $g : a\circ \to (b\circ \to c)$. We find that

$$\mathbf{eval} \circ (\mathbf{curry}(f) \otimes b) = f$$

and

$$\mathbf{curry}(\mathbf{eval} \circ (g \otimes b)) = g.$$

This shows that our category of retracts is a *Cartesian closed category*, which means roughly that product spaces and function spaces within the category interact harmoniously.

Formalization. The facts below package pairing projections, Scott's membership clause (ii) for $\otimes$, and the mediating existence/uniqueness that make $\otimes$ a categorical product. Write $h = (f \otimes g) \circ \mathbf{diag} \circ c$ for the mediating composite of the prior peer; the combinators $\mathbf{fst}$, $\mathbf{snd}$, $\mathbf{diag}$ are as in (4.14)–(4.16). Clauses (i), (iii), (iv) and the numbered equations (4.17)–(4.25) are recorded elsewhere.

Theorem (`theorem_4_4.ii`). Pairing recovers its components: $\langle x, y\rangle_0 = x$ and $\langle x, y\rangle_1 = y$.

Proof. The two coordinates of a length-2 sequence. ■

Theorem (`theorem_4_4.typed_iff`). $u : a \otimes b$ if and only if $u = \langle u_0, u_1\rangle$ with $u_0 : a$ and $u_1 : b$.

Proof. ($\Rightarrow$) Fixed-pointness under $a \otimes b$ rewrites u as $\langle a(u_0), b(u_1)\rangle$; projecting both sides yields $u_i = a(u_i)$ (resp. b), and substituting those equalities back gives the displayed pairing. ($\Leftarrow$) From $u = \langle u_0, u_1\rangle$ and the two typings, $(a \otimes b)(u) = \langle a(u_0), b(u_1)\rangle = \langle u_0, u_1\rangle = u$. ■

Theorem (`theorem_4_4.med`). If $f : c\circ \to a$ and $g : c\circ \to b$, then $h : c\circ \to (a \otimes b)$, $\mathbf{fst} \circ h = f$, and $\mathbf{snd} \circ h = g$.

Proof. Pointwise, $h(x) = \langle f(c(x)), g(c(x))\rangle$; applying $a \otimes b$ (with c a retract and the typings of f and g) returns the same pair, so h is typed into the product arrow. Composing with $\mathbf{fst}$ (resp. $\mathbf{snd}$) peels the first (resp. second) coordinate and uses that f (resp. g) already restricts along c. ■

Theorem (`theorem_4_4.med_unique`). Any $h' : c\circ \to (a \otimes b)$ with $\mathbf{fst} \circ h' = f$ and $\mathbf{snd} \circ h' = g$ equals h.

Proof. At each x, typing into $a \otimes b$ forces $h'(x) = \langle a(h'(c(x))_0), b(h'(c(x))_1)\rangle$; the projection hypotheses identify those coordinates with $f(x)$ and $g(x)$, matching $(f \otimes g)(\mathbf{diag}(c(x)))$. ■

Theorem (`theorem_4_4`). Pairing projections hold for all x, y, and $\bot$ is a retract.

Proof. The projection identity just proved, together with the known retract $\bot$. ■

`theorem_4_4.lean`

3.5.16 Theorem 4.5 ✓

THEOREM 4.5 (The sum theorem). Suppose a, b, a', b' are retracts. Then we have:

(i) $a \oplus b$ is a retract, and it is always strict;

(ii) $u : a \oplus b$ iff $u = \bot$ or $u = \top$ or ($u = \langle 0, u_1 \rangle$ and $u_1 : a$) or ($u = \langle 1, u_1 \rangle$ and $u_1 : b$);

(iii) if $a \sqsubseteq a'$ and $b \sqsubseteq b'$, then $a \oplus b \sqsubseteq a' \oplus b'$;

(iv) if $f : a\circ \to b$ and $f' : a'\circ \to b'$, then $f \oplus f' : a \oplus a'\circ \to b \oplus b'$.

There are several combinators associated with $\oplus$:

$$(4.26) \quad \mathbf{inleft} = \lambda x.\, \langle 0, x \rangle;$$

$$(4.27) \quad \mathbf{inright} = \lambda x.\, \langle 1, x \rangle;$$

$$(4.28) \quad \mathbf{outleft} = \lambda u.\, u_0 \supset u_1,\, \bot;$$

$$(4.29) \quad \mathbf{outright} = \lambda u.\, u_0 \supset \bot,\, u_1;$$

$$(4.30) \quad \mathbf{which} = \lambda u.\, u_0;$$

$$(4.31) \quad \mathbf{out} = \lambda u.\, u_1.$$

(The last two are the same as **fst** and **snd**, but they will be used differently.) We find:

$$(4.32) \quad (a \oplus b) \circ \mathbf{inleft} \circ a : a\circ \to (a \oplus b);$$

$$(4.33) \quad (a \oplus b) \circ \mathbf{inright} \circ b : b\circ \to (a \oplus b);$$

$$(4.34) \quad a \circ \mathbf{outleft} \circ (a \oplus b) : (a \oplus b)\circ \to a;$$

$$(4.35) \quad b \circ \mathbf{outright} \circ (a \oplus b) : (a \oplus b)\circ \to b;$$

$$(4.36) \quad \mathbf{which} \circ (a \oplus b) : (a \oplus b)\circ \to \mathbf{bool};$$

$$(4.37) \quad a \circ \mathbf{out} \circ (a \oplus a) : (a \oplus a)\circ \to a;$$

where a and b are retracts. Most of these facts as they stand are trivial until one sets down the relations between all these maps; but there are too many to put them down here. Note, however, if a, b, and c are retracts and $f : a\circ \to c$ and $g : b\circ \to c$, then if we let

$$h = c \circ \mathbf{out} \circ (f \oplus g),$$

we have:

$$h : (a \oplus b)\circ \to c,$$

and

$$h \circ \mathbf{inleft} = f \quad \text{and} \quad h \circ \mathbf{inright} = g.$$

But, though h exists, it is not unique. So $a \oplus b$ is not the categorical sum (coproduct). The author does not know a neat categorical characterization of this operator.

There would be no difficulty in extending $\otimes$ and $\oplus$ to more factors by expanding the range of indices from $0, 1$ to $0, 1, \ldots, n-1$. The explicit formulae need not be given; but if we write $a_0 \otimes a_1 \otimes \cdots \otimes a_{n-1}$, we intend this expanded meaning rather than the iterated binary product.

To understand sums and other facts about retracts, consider the least fixed point of this equation:

$$(4.38) \quad \mathbf{tree} = \mathbf{nil} \oplus (\mathbf{tree} \otimes \mathbf{tree}).$$

To be certain that **tree** is a retract, we need a general theorem:

Proofs of Theorems 4.3–4.5. We will not give full details as all the parts of these theorems are direct calculations. Consider by way of example Theorem 4.3(i). We find:

$$\begin{aligned}(a\circ \to b) \circ (a\circ \to b) &= \lambda u.\, b \circ (b \circ u \circ a) \circ a \\ &= \lambda u.\, b \circ u \circ a \\ &= a\circ \to b,\end{aligned}$$

provided that a and b are retracts. A very similar computation would verify part (iv), if one writes out the composition:

$$(a\circ \to b') \circ (f\circ \to f') \circ (b\circ \to a')$$

and uses the equations:

$$f = b \circ f \circ a \quad \text{and} \quad f' = b' \circ f' \circ a'.$$

Formalization. The Lean owned by this note is a thin packaging of the $\bot$-case that seeds strictness of $\oplus$. The sum operator itself is

$$a \oplus b = \mathbf{graph}\big(u \mapsto u_0 \sqsupset \langle 0,\, a(u_1)\rangle,\, \langle 1,\, b(u_1)\rangle\big)$$

(using the doubly strict conditional of (4.4)). The full packaging of Scott's (i)–(ii) lives in `theorem_4_5_sum` (Functionality); clauses (iii)–(iv) and (4.32)–(4.37) are companion lemmas.

Theorem (`theorem_4_5`). For any a, b,

$$\bot \sqsupset \langle 0,\, a(\bot)\rangle,\, \langle 1,\, b(\bot)\rangle \;=\; \bot,$$

and $\bot$ is a retract.

Proof. The first conjunct is the empty-tag law for $\sqsupset$: a pure bottom discriminator yields $\bot$ regardless of the two branches. The second is the known retract $\bot = \bot \circ \bot$. ■

3.5.17 Expression interpreter ✓

Any combination of retract preserving functors can be used in this game. For example:

$$(4.39) \quad \mathbf{lamb} = \mathbf{int} \oplus (\mathbf{lamb} \circ \to \mathbf{lamb}).$$

This looks innocent, but the range of **lamb** would give a quite different and not unattractive model for the λ-calculus (plus arithmetic). What we do to investigate this model is to modify LAMBDA slightly by replacing the ternary conditional $z \supset x, y$ by a quaternary one $w \supset x, y, z$; otherwise the syntax of the language remains the same. The semantics, however, is a little more complex.

Let us use τ, σ, ρ, θ as syntactical variables for expressions in the modified language. The semantics is provided by a function $\mathcal{H}$ that maps the expressions of the language to their values in (the range of) **lamb**. To be completely rigorous we

also have to confront the question of free and bound variables. For simplicity let us index the variables of the language by integers, and let us take the variables to be $v_0, v_1, v_2, \ldots, v_n, \ldots$. We cannot simply evaluate out an expression τ to its value $\mathcal{H}[\![\tau]\!]$ until we know the values of the free variables in τ. The values of these variables will be given by an "environment" t which can be construed as a *sequence* of values in **lamb**. We can restrict these environments to the retract:

$$(4.40) \quad \mathbf{env} = \lambda t.\, \mathbf{lamb} \circ \mathbf{seq}(t).$$

When $t : \mathbf{env}$, then $t_n : \mathbf{lamb}$ is the value that the environment gives to the variable v_n. We also need to employ a transformation on environments as follows:

$$(4.41) \quad t[x/n] = \lambda m \in \omega.\, \mathbf{eq}(n)(m) \supset x,\, t_m.$$

Here **eq** is the primitive recursive function that is 0, if n, m are equal, and is 1, otherwise, for $n, m \in \omega$. The effect of $t[x/n]$ is to replace the nth term of the sequence t by the value of x, otherwise to leave the rest of the sequence unchanged. To correspond with our use of very simple variables we have selected a simple notion of environment: in the semantics of more general languages it is customary to regard an environment as a function from the set of variables into the domain of denotable values.

The correct way to evaluate a term τ given an environment t is to find $\mathcal{H}[\![\tau]\!](t)$. We use the brackets $[\![$ and $]\!]$ here simply as an aid to the eye in keeping the syntactical part separated from the rest. The environment enters as a function-argument in the usual way; thus we shall have:

$$(4.42) \quad \mathcal{H}[\![\tau]\!] : \mathbf{env} \to \mathbf{lamb}.$$

$$\begin{aligned}
\mathcal{H}[\![v_n]\!](t) &= t_n \\
\mathcal{H}[\![0]\!](t) &= \mathbf{inleft}(0) \\
\mathcal{H}[\![\tau + 1]\!](t) &= \mathbf{which}(\mathcal{H}[\![\tau]\!](t) \supset \mathbf{inleft}(\mathbf{out}(\mathcal{H}[\![\tau]\!](t)) + 1),\, \bot) \\
\mathcal{H}[\![\tau - 1]\!](t) &= \mathbf{which}(\mathcal{H}[\![\tau]\!](t) \supset \mathbf{inleft}(\mathbf{out}(\mathcal{H}[\![\tau]\!](t)) - 1),\, \bot) \\
\mathcal{H}[\![\theta \supset \tau, \sigma, \rho]\!](t) &= \mathbf{lamb}(\mathbf{which}(\mathcal{H}[\![\theta]\!](t) \supset (\mathbf{out}(\mathcal{H}[\![\theta]\!](t)) \supset \mathcal{H}[\![\tau]\!](t),\, \mathcal{H}[\![\sigma]\!](t)),\, \mathcal{H}[\![\rho]\!](t))) \\
\mathcal{H}[\![\tau(\sigma)]\!](t) &= \mathbf{which}(\mathcal{H}[\![\tau]\!](t) \supset \bot,\, \mathbf{out}(\mathcal{H}[\![\tau]\!](t))(\mathcal{H}[\![\sigma]\!](t))) \\
\mathcal{H}[\![\lambda v_n.\, \tau]\!](t) &= \mathbf{inright}(\lambda x : \mathbf{lamb}.\, \mathcal{H}[\![\tau]\!](t[x/n])).
\end{aligned} \tag{4.43}$$

A good question is: why does $\mathcal{H}$ exist? The answer is: because of the fixed-point theorem.

If we rewrite the semantic equations $\mathcal{H}[\![\tau]\!](t) = (\dots)$ in (43) by the equation $\mathcal{H}[\![\tau]\!] = \lambda t : \mathbf{env}\,(\dots)$, then $\mathcal{H}$ is seen to be a function from expressions to values in **lamb**. As the range of **lamb** is contained in $\mathbf{P}\omega$, we can say more broadly that $\mathcal{H} \in \mathbf{P}\omega^{\mathbf{Exp}}$, where **Exp** is the syntactical set of expressions and the exponential notation designates the set of *all* functions from **Exp** into $\mathbf{P}\omega$. This function set is a complete lattice because $\mathbf{P}\omega$ is. Therefore if we read (4.43) as a definition by cases on **Exp**, then we can find $\mathcal{H}$ as a suitable fixed point in the complete lattice $\mathbf{P}\omega^{\mathbf{Exp}}$. Indeed it is the fixed point of a continuous operator.

Actually we can regard **Exp** as being a subset of $\mathbf{P}\omega$ to avoid dragging in other lattices. What we need is another recursive definition of a data type:

$$(4.44)\quad \mathbf{exp} = \mathbf{int} \oplus \mathbf{nil} \oplus \mathbf{exp} \oplus \mathbf{exp} \oplus (\mathbf{exp} \otimes \mathbf{exp} \otimes \mathbf{exp} \otimes \mathbf{exp}) \\ \oplus(\mathbf{exp} \otimes \mathbf{exp}) \oplus (\mathbf{int} \otimes \mathbf{exp}).$$

Note that there are as many summands in (4.44) as there are clauses in (4.43). We can think of **exp** as giving the "abstract" syntax of the language. We use the integers to index the variables and the **nil** element to stand for the individual constant. Read (4.44) as saying that every expression is *either* a variable *or* a constant *or* the successor of an expression *or* the predecessor of an expression *or* the conditional formed from a tuple of expressions *or* the abstraction formed from a pair of a variable and an expression. We do not need in (4.44) to introduce special "symbols" for the successor, application, etc., because the separation by cases given by the $\oplus$ operation is sufficient to make the distinctions. (That is why the syntax is "abstract".) The point is that for recursive definitions it does not matter how we make the distinctions as long as they can be made. From this new point of view, we could rewrite (4.43) so as to show:

$$(4.45)\quad \mathcal{H} : \mathbf{exp} \to (\mathbf{env} \to \mathbf{lamb}),$$

which is clearly more satisfactory—especially as it is now clear that $\mathcal{H}$ is *computable*. And this is a method that can be generalized to many other languages. The method also shows why it is useful to allow *function spaces* as particular data types.

Formalization. Abstract syntax, its encoding into the **exp** retract, the tagged continuous step clauses of the interpreter, the least fixed point packaging, and the typing identity (4.45).

Definition (`LambTerm`). An expression is a variable index, zero, a successor or predecessor of an expression, a quaternary conditional of four expressions, an application of two expressions, or an abstraction of an index and a body.

Definition (`encodeExp`). Encode each constructor by the corresponding summand of (4.44): tag 0 with a numeral, tag 1 with $\perp$, tags 2–3 with a recursive encoding, tag 4 with a four-tuple of encodings, tag 5 with a pair of encodings, and tag 6 with a numeral paired to a body encoding.

Theorem (`encodeExp.typed`). Every encoding is typed into **exp**.

Proof. Induction on syntax, using the fixed-point equation for **exp** and the typing laws for the seven summands. ■

Definition (`expTag`). The tag of an encoded expression is its application to 0.

Definition (`expPayload`). The payload of an encoded expression is its application to 1.

Definition (`hApply`). Apply an interpreter candidate H to an encoded expression e at an environment t.

Theorem (`hApply.isScottContinuous_H`). Application is Scott-continuous in the interpreter candidate.

Proof. Compose left-continuity of application twice. ■

Theorem (`hApply.isScottContinuous_e`). Application is Scott-continuous in the encoded expression.

Proof. Compose left-continuity of application with continuity of the candidate. ■

Theorem (`hApply.payload_isScottContinuous_e`). Applying H at the ith component of the payload is Scott-continuous in the encoding.

Proof. Compose the previous continuity in e with continuity of payload projection. ■

Definition (`hVar`). The variable clause looks up the payload of e in the environment t.

Theorem (`hVar.isScottContinuous_t`). The variable clause is Scott-continuous in the environment.

Proof. Left-continuity of application at a fixed payload. ■

Theorem (`hVar.isScottContinuous_e`). The variable clause is Scott-continuous in the encoding.

Proof. Compose continuity of the environment with continuity of the payload. ■

Definition (`hZero`). The zero clause is the left injection of the numeral 0.

Definition (`hApp`). The application clause tests the tag of the value of the operator payload: on a right injection it applies the extracted function to the value of the operand payload; otherwise it yields $\bot$.

Theorem (`hApp.isScottContinuous_H`). The application clause is Scott-continuous in the interpreter candidate.

Proof. Continuity of the ternary conditional along continuous tag tests and continuous applications of H. ■

Theorem (`hApp.isScottContinuous_t`). The application clause is Scott-continuous in the environment.

Proof. Continuity of the conditional along continuous evaluation of the two payloads. ■

Theorem (`hApp.isScottContinuous_e`). The application clause is Scott-continuous in the encoding.

Proof. Continuity of the conditional along continuous payload projections. ■

Definition (`hSucc`). The successor clause tests the tag of the recursive value: on a left injection it re-injects the successor of the payload; otherwise it yields $\bot$.

Theorem (`hSucc.isScottContinuous_H`). The successor clause is Scott-continuous in the interpreter candidate.

Proof. Continuity of the conditional along continuous application of H, extraction, and successor. ■

Theorem (`hSucc.isScottContinuous_t`). The successor clause is Scott-continuous in the environment.

Proof. Continuity of the conditional along continuous evaluation of the payload. ■

Theorem (`hSucc.isScottContinuous_e`). The successor clause is Scott-continuous in the encoding.

Proof. Continuity of the conditional along continuous payload projection. ■

Definition (`hPred`). The predecessor clause is as for successor, with predecessor in place of successor.

Theorem (`hPred.isScottContinuous_H`). The predecessor clause is Scott-continuous in the interpreter candidate.

Proof. As for successor, with continuity of predecessor. ■

Theorem (`hPred.isScottContinuous_t`). The predecessor clause is Scott-continuous in the environment.

Proof. As for successor. ■

Theorem (`hPred.isScottContinuous_e`). The predecessor clause is Scott-continuous in the encoding.

Proof. As for successor. ■

Definition (`hCond`). The quaternary conditional clause evaluates the four payload components and selects via the **lamb**-wrapped nested conditional of (4.43).

Theorem (`hCond.isScottContinuous_H`). The conditional clause is Scott-continuous in the interpreter candidate.

Proof. Continuity of application of **lamb** along continuous nested conditionals of continuous applications of H. ■

Theorem (`hCond.isScottContinuous_t`). The conditional clause is Scott-continuous in the environment.

Proof. Continuity of **lamb**-application along continuous evaluation of the four payloads. ■

Theorem (`hCond.isScottContinuous_e`). The conditional clause is Scott-continuous in the encoding.

Proof. Continuity of **lamb**-application along continuous payload projections. ■

Definition (`hLam`). The abstraction clause right-injects the graph of $x \mapsto H$ applied to the body payload at the environment updated at the bound index by x.

Theorem (`hLam.isScottContinuous_H`). The abstraction clause is Scott-continuous in the interpreter candidate.

Proof. Continuity of right injection of a graph whose body is continuous in H. ■

Theorem (`hLam.isScottContinuous_t`). The abstraction clause is Scott-continuous in the environment.

Proof. Continuity of right injection of a graph continuous in the updated environment. ■

Theorem (`hLam.isScottContinuous_e`). The abstraction clause is Scott-continuous in the encoding.

Proof. Continuity of right injection along continuous payload projections into the update. ■

Definition (`Hstep`). The tagged step nests doubly strict conditionals on iterated predecessors of the tag, dispatching to the variable, zero, successor, predecessor, conditional, application, and abstraction clauses, with $\top$ as the residual.

Theorem (`Hstep.tag0`). On a tag-0 injection with payload x, the step returns $t(x)$.

Proof. Unfold the tag cascade at numeral 0. ■

Theorem (`Hstep.tag1`). On a tag-1 injection, the step returns the zero clause.

Proof. Unfold the tag cascade at numeral 1. ■

Theorem (`Hstep.tag2`). On a tag-2 injection, the step returns the successor clause at that encoding.

Proof. Unfold the tag cascade at numeral 2. ■

Theorem (`Hstep.tag3`). On a tag-3 injection, the step returns the predecessor clause at that encoding.

Proof. Unfold the tag cascade at numeral 3. ■

Theorem (`Hstep.tag4`). On a tag-4 injection, the step returns the conditional clause at that encoding.

Proof. Unfold the tag cascade at numeral 4. ■

Theorem (`Hstep.tag5`). On a tag-5 injection, the step returns the application clause at that encoding.

Proof. Unfold the tag cascade at numeral 5. ■

Theorem (`Hstep.tag6`). On a tag-6 injection, the step returns the abstraction clause at that encoding.

Proof. Unfold the tag cascade at numeral 6. ■

Theorem (`Hstep.isScottContinuous_H`). The step is Scott-continuous in the interpreter candidate.

Proof. Nest continuity of the doubly strict conditional along continuous clauses in H. ■

Theorem (`Hstep.isScottContinuous_t`). The step is Scott-continuous in the environment.

Proof. Nest continuity of the doubly strict conditional along continuous clauses in t. ■

Theorem (`Hstep.isScottContinuous_e`). The step is Scott-continuous in the encoding.

Proof. Nest continuity of the doubly strict conditional along continuous tag maps and continuous clauses in e. ■

Definition (`HF`). The continuous operator on interpreter candidates sends H to the graph of $e \mapsto$ the graph of $t \mapsto \mathrm{Hstep}(H, e, t)$.

Theorem (`HF.inner_isScottContinuous`). For fixed H, the map $e \mapsto$ the graph of $t \mapsto \mathrm{Hstep}(H, e, t)$ is Scott-continuous.

Proof. Graph of a family continuous in e for each t. ■

Theorem (`HF.isScottContinuous`). HF is Scott-continuous.

Proof. Graph of a family continuous in H for each e, using continuity of the step in H. ■

Theorem (`HF.app`). Applying $\mathrm{HF}(H)$ to e recovers the graph of $t \mapsto \mathrm{Hstep}(H, e, t)$.

Proof. The β-law for the inner continuous graph. ■

Theorem (`HF.app2`). Applying that graph at t recovers $\mathrm{Hstep}(H, e, t)$.

Proof. The previous application law and the β-law for the step in t. ■

Definition (`Hinterp`). The compositional semantics (4.43): variables look up the environment; zero is the left injection of 0; successor and predecessor re-inject after testing; the quaternary conditional is **lamb**-wrapped; application tests the operator tag; abstraction right-injects the graph of the body in an updated environment.

Theorem (`Hinterp.isScottContinuous`). For each expression, compositional interpretation is Scott-continuous in the environment.

Proof. Induction on syntax, assembling continuity of conditionals, injections, **lamb**, graphs, and environment update. ■

Definition (`Hfun`). The interpreter is the least fixed point of HF.

Theorem (`Hfun.fixed`). $\mathrm{HF}(\mathrm{Hfun}) = \mathrm{Hfun}$.

Proof. The fixed-point theorem for a Scott-continuous operator. ■

Theorem (`Hfun.app2`). Applying Hfun twice recovers the step at Hfun.

Proof. Congruence from the fixed-point equation and the double application law for HF. ■

Theorem (`Hfun.interp`). On an encoded expression, Hfun agrees with compositional interpretation.

Proof. Induction on syntax: tag laws select the matching clause, and inductive hypotheses rewrite recursive applications. ■

Theorem (`Hfun.decode`). Applying Hfun to an encoding yields the graph of compositional interpretation.

Proof. The fixed-point application law yields the step graph; pointwise the previous agreement rewrites it to compositional interpretation. ■

Definition (`Htyped`). The retract-arrow packaging of compositional interpretation as an element of $\mathbf{env}\circ \to \mathbf{lamb}$.

Theorem (`Htyped.app`). Applying the packaging at t yields **lamb** of compositional interpretation at the **env**-projection of t.

Proof. The retract-arrow application law and the β-law for continuous compositional interpretation. ■

Theorem (`Htyped.typed`). The packaging is typed into $\mathbf{env}\circ \to \mathbf{lamb}$.

Proof. Typing of retract-arrow application. ■

Definition (`Hcomb`). $\mathcal{H}$ as the retract-arrow packaging of Hfun into $\mathbf{exp}\circ \to (\mathbf{env}\circ \to \mathbf{lamb})$.

Theorem (`Hcomb.app`). Applying $\mathcal{H}$ at e yields the **env–lamb** packaging of Hfun at the **exp**-projection of e.

Proof. The retract-arrow application law. ■

Theorem (`Hcomb.typed`). $\mathcal{H}$ is typed into $\mathbf{exp}\circ \to (\mathbf{env}\circ \to \mathbf{lamb})$.

Proof. Typing of retract-arrow application at the three retracts. ■

Theorem (`eq_4_45`). An encoding is typed into **exp**; its compositional packaging is typed into $\mathbf{env}\circ \to \mathbf{lamb}$; and $\mathcal{H}$ on that encoding equals the compositional packaging.

Proof. Encoding typing, packaging typing, and decode after projecting the encoding through **exp**. ■

3.5.18 Theorem 4.6 ✓

THEOREM 4.6 (The limit theorem).

Limit. *Suppose F is a continuous function that maps retracts to retracts and let $c = \mathbf{Y}(F)$. Then c is also a retract.*

inverse_limit. *If in addition F maps strict retracts to strict retracts and is monotone in the sense that $a \sqsubseteq b$ implies $F(a) \sqsubseteq F(b)$ for all (strict) retracts a and b, then the range of c is homeomorphic to the inverse limit of the ranges of the strict retracts $F^n(\bot)$ for $n \in \omega$.*

This can be applied to the case of (4.38) where $F = \lambda z.\, \mathbf{nil} \oplus (z \otimes z)$. Thus we can analyze **tree** as an inverse limit. This approach has the great advantage over the earlier method of the author where limits were required in showing that **tree** exists. Here we use **Y** to give existence at once, and then apply Theorems 4.3–4.5 to figure out the nature of the retract.

In Theorem 4.6, the fact that c is a retract can be reasoned as follows: $\bot$ is a

retract. Thus each $F^n(\bot)$ is a retract. We compute:

$$c \circ c = \bigcup\{F^n(\bot) \mid n \in \omega\} \circ \bigcup\{F^n(\bot) \mid n \in \omega\}$$

$$= \bigcup\{F^n(\bot) \circ F^n(\bot) \mid n \in \omega\} \quad \text{(Note: same } n.\text{)}$$

$$= \bigcup\{F^n(\bot) \mid n \in \omega\} = c.$$

In case F is monotone and preserves strictness, then we can argue that each $F^n(\bot) \sqsubseteq c$. The retracts $F^n(\bot)$ are the *projections* of c onto the terms of the limit. Of course $F^n(\bot) \sqsubseteq F^m(\bot)$ if $n \leq m$. The

$u : c$ can be put into a one-to-one correspondence (homeomorphism, lattice isomorphism) with the infinite sequences $\langle v_0, v_1, \ldots, v_n, \ldots\rangle$, where $v_n : F^n(\bot)$ and $v_n = F^n(\bot)(v_{n+1})$. Indeed $v_n = F^n(\bot)(u)$ and $u = \bigcup\{v_n \mid n \in \omega\}$. This is exactly the inverse limit construction.

Retreating from generalities back to the example of **tree**, we can grant that it exists and is provably a retract. Two things in its range are $\bot$ and $\top$ by Theorem 4.5(ii), but they are not so interesting. Now $\bot : \mathbf{nil}$, so by Theorem 4.5(ii) we have $\langle 0\rangle = \langle 0, \bot\rangle : \mathbf{tree}$. Let us think of this as *the* atom. What else can we have? If $x, y : \mathbf{tree}$, then $\langle x, y\rangle : \mathbf{tree} \otimes \mathbf{tree}$ and so $\langle 1, \langle x, y\rangle\rangle : \mathbf{tree}$. Thus (the range of) **tree** contains an atom and is closed under a binary operation. Note that the atomic and nonatomic trees are distinguished by **which** and that suitable constructor and destructor functions are definable on **tree**. But the space also contains infinite trees since we can solve for the least fixed point of:

$$t = \langle 1, \langle\langle 0\rangle, t\rangle\rangle$$

and $t : \mathbf{tree}$. (Why?) And there are many other examples of infinite elements in **tree**.

A point to stress in this construction is that **tree** being LAMBDA-definable is *computable*, and there are many computable functions definable on or to (the range of) **tree**. All the "structural" functions, for example, are computable. These are functions which in other languages would be called **isatom** or **construct** or **node**, and they are all easily LAMBDA-definable. Just as with $\oplus$, $\otimes$, $\circ\!\!\rightarrow$, they are not explicit in the *notation*, but they are definable nevertheless. In the case of **node**, we could use finite sequences of Boolean values to pick out or name nodes. Thus solve for $\mathbf{name} = \mathbf{nil} \oplus \mathbf{bool} \otimes \mathbf{name}$, and then give a recursive definition of:

$$\mathbf{node} : \mathbf{name}\circ\!\!\rightarrow (\mathbf{tree}\circ\!\!\rightarrow \mathbf{tree}).$$

Another example of this method can be illustrated, if the reader will recall the Gödel numbering of § 3. It will be seen that there are similarities with the **tree** construction: instead of 0 and $\mathbf{apply}(n)(m)$, **tree** uses $\langle 0\rangle$ and $\langle 1, \langle x, y\rangle\rangle$. Note, however, that Gödel numbers are *finite* while **tree** has *infinite* objects. But the infinite objects are always *limits* of finite objects, so there *are* connections. (We discuss this again in § 6.) In particular, recursive definitions on Gödel numbers, like that of **val**, have analogues on **tree**. Here is the companion of (3.7):

$$(4.46)\quad \mathbf{vaal} = \lambda x : \mathbf{tree}.\, \mathbf{which}(x) \supset \mathbf{G},\ \mathbf{vaal}(\mathbf{fst}(\mathbf{out}(x)))(\mathbf{vaal}(\mathbf{snd}(\mathbf{out}(x)))).$$

We have $\mathbf{vaal} : \mathbf{tree} \rightarrow \mathbf{id}$, where of course (4.46) is taken as defining **vaal** as the least fixed point. This is an example of a computable function between effectively given retracts. The LAMBDA-definable elements of $\mathbf{P}\omega$ are the computable elements in the range of **vaal**.

We have discussed the category of retracts and continuous maps, but if they are all LAMBDA-definable, then they fall within the countable model **RE**. Thus there is *another* category of effectively given retracts and effectively given continuous maps. (Examples: **tree**, **id**, **vaal**, and all those retracts and maps generated by $\oplus$, $\otimes$, and $\circ\!\!\rightarrow$.) This category seems to deserve the status of a generalized recursion theory; though this is not to say that as yet very much is known about it. In fact, the proper formulation may require an enriched category rather than a restricted one. Thus instead of confining attention to the computable retracts and computable maps, it might be better to use the full category with all maps and to single out the computable ones (also maybe the finite ones) by special predicates. In effect we have avoided any methodological decisions by working in

the universal space $\mathbf{P}\omega$ and by *defining* a notion when required—if possible with the aid of LAMBDA. This makes it possible to give all the necessary definitions and to prove the theorems without at first having to worry about axiomatic problems.

5. Closure operations and algebraic lattices.

The main point of the proof of Theorem 4.6 has already been given in the text.

Formalization. Scott's two sentences are two theorems, `theorem_4_6.Limit` and `theorem_4_6.inverse_limit`; `theorem_4_6` is their conjunction. The witnessing order isomorphism is the definition `theorem_4_6.InverseLimit`. Downstream existence for **tree**, **lamb**, and **exp** uses `theorem_4_6.Limit`.

Theorem (`theorem_4_6.Limit`). If F is Scott-continuous and sends retracts to retracts, then every iterate $F^n(\bot)$ is a retract, and so is $c = \mathbf{Y}(F)$.

Proof. Induction from $\bot$ gives the iterates. For c: identify $\mathbf{Y}(F)$ with $\operatorname{fix} F = \bigcup_n F^n(\bot)$ (Theorem 2.5); the union of a chain of retracts is a graph, and application of that graph is idempotent on the union, so $c = c \circ c$. ■

Definition (`theorem_4_6.InverseLimit`). The order isomorphism

$$\operatorname{Fix}(\operatorname{fix} F) \;\simeq_o\; \varprojlim_n \operatorname{range}(F^n(\bot))$$

under the strictness and monotonicity hypotheses, with projections $u \mapsto F^n(\bot)(u)$ and reconstruction $u = \bigcup_n v_n$.

Proof. Assemble `fixedToInverseLimit` / `inverseLimitToFixed` and the union/projection identities. ■

Theorem (`theorem_4_6.inverse_limit`). Under those same extra hypotheses, such an order isomorphism exists (the ranges are homeomorphic / lattice-isomorphic in Scott's sense).

Proof. ⟨theorem_4_6.InverseLimit⟩. ■

Theorem (`theorem_4_6`). `theorem_4_6.Limit` and `theorem_4_6.inverse_limit`.

Proof. ⟨`theorem_4_6.Limit`, `theorem_4_6.inverse_limit`⟩. ■

3.6 Closure operations and algebraic lattices

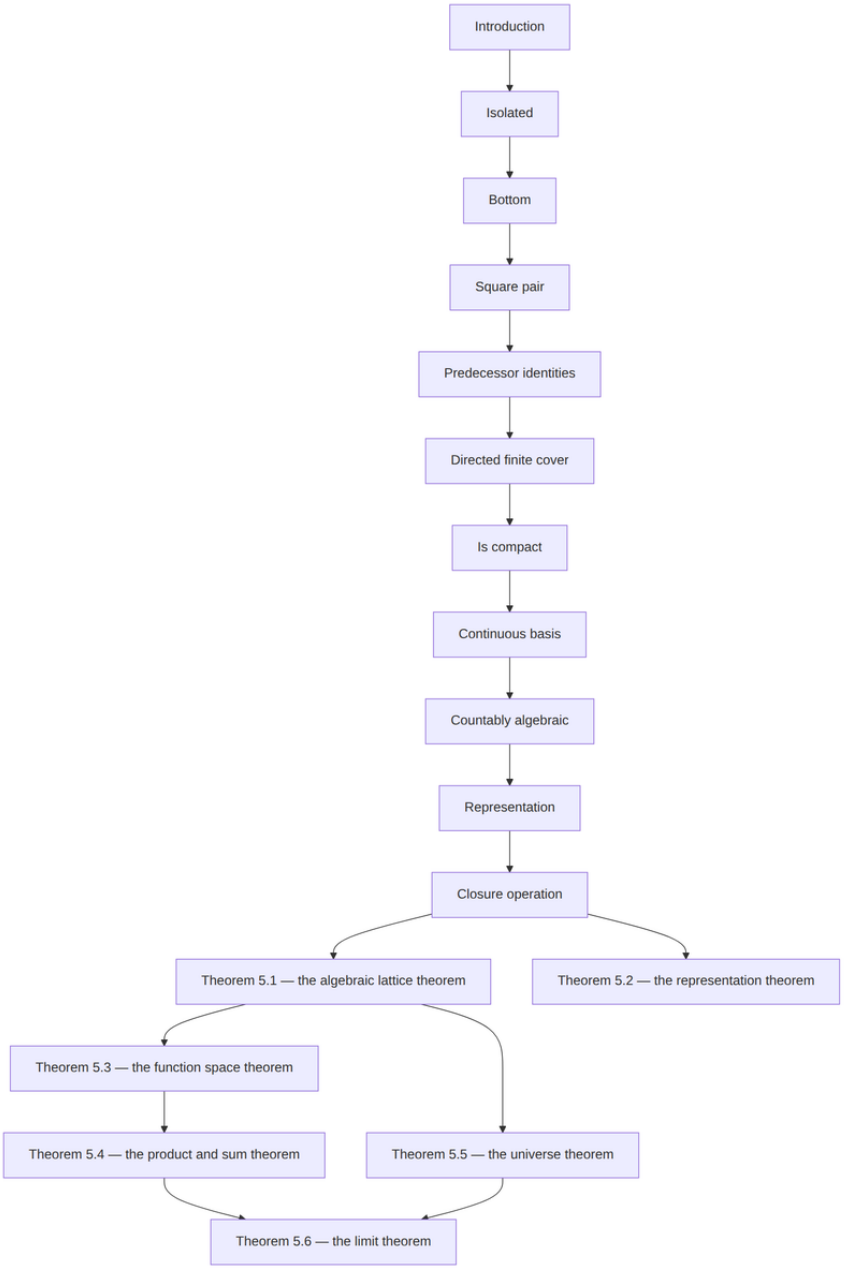

Figure 35: Closure operations and algebraic lattices.

3.6.1 Introduction ✓

Algebraic lattices and closure operations predate the paper: [30] for the lattices, [31] for the closures. Per Martin-Löf and Peter Hancock suggested that the continuous closures form a universe, and the construction of $\mathbf{V}$ is essentially theirs. The limit theorem is Scott's.

Given any family of (finitary) operations on a set (say, ω) there is a closure operation defined on the subsets of that set obtained by forming the *least subset* including the given elements and *closed* under the operations. Examples are very familiar from algebra: the subgroup generated by a set of elements, the subspace spanned by a set of vectors, the convex hull of a set of geometric points. We simplify matters here by restricting attention to closures operating on sets in $\mathbf{P}\omega$, but the idea is quite general. The main point about these "algebraic" closure operations—as distinguished from topological closure operations—is that they are *continuous*. Thus, in the case of subgroups, if an element belongs to the subgroup generated by some elements, then it also belongs to the subgroup generated by *finitely* many of them. In the context of $\mathbf{P}\omega$ we can state the characteristic condition very simply.

3.6.2 Isolated ✓

Isolated elements of $\mathbf{P}\omega$ are the finite (compact) basis sets e_n.

Formalization.

Definition (`Isolated`). An element $x \in \mathbf{P}\omega$ is isolated when $x = e_n$ for some $n \in \omega$.

Proof. The class packages that existential; `e` is the standard finite-set coding on $\mathbf{P}\omega$. ■

`Isolated.lean`

```
module

public import DomainTheory.DataTypesAsLattices.Pomega.e
@[expose] public section

namespace DomainTheory.DataTypesAsLattices

class Isolated (x : Pomega) : Prop where
  out : ∃ n, x = e n

end DomainTheory.DataTypesAsLattices
```

3.6.3 Bottom ✓

Elementary identities for $\bot$ in $\mathbf{P}\omega$: it is distinct from $\top$, every nonempty set meets some element, and unions with $\bot$ are trivial.

Theorem (`botElem.ne_top`). $\top \neq \bot$ in $\mathbf{P}\omega$.

Proof. Otherwise $0 \in \bot$; but $\bot$ is empty. ■

Theorem (`botElem.exists_mem`). If $x \neq \bot$, then some natural number belongs to x.

Proof. Contrapositively, a set with no members is $\bot$. ■

Theorem (`botElem.union_empty`). $x \cup \bot = x$.

Proof. Union with the empty set does not change x. ■

Theorem (`botElem.empty_union`). $\bot \cup x = x$.

Proof. The empty set is a unit for union on the left as well. ■

Theorem (`botElem.ne_ofNat_zero`). $\bot \neq 0$ in $\mathbf{P}\omega$.

Proof. Otherwise $0 \in \bot$; but $\bot$ is empty. ■

`botElem.lean`

```
module

public import DomainTheory.DataTypesAsLattices.Pomega.Pomega
public import DomainTheory.DataTypesAsLattices.Lambda.Language
@[expose] public section

namespace DomainTheory.DataTypesAsLattices

namespace botElem

theorem ne_top : (topElem : Pomega) = botElem := by
  intro h
  have h0 : (0 : ℕ) ∈ (botElem : Pomega) := h ▸ Set.mem_univ 0
  simp [botElem] at h0

theorem ne_ofNat_zero : botElem = ofNat 0 := by
  intro h
  have : (0 : ℕ) ∈ botElem := by rw [h]; simp [ofNat]
  exact (mem_botElem 0).mp this

theorem exists_mem {x : Pomega} (h : x = botElem) : ∃ m, m ∈ x := by
  by_contra hc
  refine h ?_
  ext n
  simp only [mem_botElem, iff_false]
  exact fun hn => hc ⟨n, hn⟩

theorem union_empty (x : Pomega) : x ∪ botElem = x := Set.union_empty x

theorem empty_union (x : Pomega) : botElem ∪ x = x := Set.empty_union x

end botElem

end DomainTheory.DataTypesAsLattices
```

3.6.4 Square pair ✓

The square pairing $x \square y$ interlaces the elements of x and y by parity of codes.

Definition (`squarePair`). For $x, y \subseteq \omega$,

$$x \square y \;=\; \{2n \mid n \in x\} \;\cup\; \{2m+1 \mid m \in y\}.$$

Proof. Evens carry the first component and odds the second; every code has a unique parity, so the two halves do not interfere. ■

`squarePair.lean`

```
module

public import DomainTheory.DataTypesAsLattices.Pomega.Pomega
public import Mathlib.Tactic.ToAdditive
@[expose] public section

namespace DomainTheory.DataTypesAsLattices
```

```
def squarePair (x y : Pomega) : Pomega :=
  {k | (∃ n ∈ x, k = 2 * n) ∨ (∃ m ∈ y, k = 2 * m + 1)}

end DomainTheory.DataTypesAsLattices
```

3.6.5 Predecessor identities ✓

Predecessor identities used when shifting codes: $\mathrm{pred}(\mathrm{succ}\, x) = x$ and pred preserves unions.

Formalization. Library facts live under `predSet` in `Lambda/predSet_more.lean`.

Theorem (`predSet.isScottContinuous`). The map $x \mapsto \mathrm{predSet}(x)$ is Scott-continuous on $\mathbf{P}\omega$.

Proof. Membership of k in $\mathrm{predSet}(x)$ is witnessed by a finite e-approximation (namely e_{2^k+1}), so the Scott-union characterization applies both ways. ■

Theorem (`predSet.ofNat_succ`). $\mathrm{predSet}(j+1) = j$ as numerals.

Proof. Unfold `ofNat` and `predSet`; the predecessor of the singleton $\{j+1\}$ is $\{j\}$. ■

Theorem (`predSet.succSet`). $\mathrm{predSet}(\mathrm{succSet}\, x) = x$.

Proof. Elements of $\mathrm{succSet}\, x$ are successors of members of x; injectivity of succ recovers x, and conversely every $k \in x$ contributes $k+1$. ■

Theorem (`predSet.union`). $\mathrm{predSet}(x \cup y) = \mathrm{predSet}(x) \cup \mathrm{predSet}(y)$.

Proof. Unfold `predSet`; predecessor distributes over union of sets of naturals. ■

3.6.6 Directed finite cover ✓

A finite subset of the union of a directed family of fixpoints is covered by a single member of the family.

Theorem (`directed_finite_cover_subset`). Let A be a directed set of fixed points of a continuous map on $\mathbf{P}\omega$. If a finite $t \subseteq \omega$ is contained in the union of the members of A, then some single $z \in A$ already contains t.

Proof. Directedness of A as fixed points is the same as directedness of the underlying sets, so the ordinary finite-cover lemma for directed families applies. ■

    simpa [Fixpoints.vals] using hsub)

end DomainTheory.DataTypesAsLattices
```

3.6.7 Is compact ✓

An element of a complete lattice is compact when it is way-below itself.

Definition (`IsCompact`). In a complete lattice, x is compact when $x \ll x$: whenever a directed set has supremum at least x, some single member of the set already lies above x.

Proof. Compactness is the diagonal case of the way-below relation. ■

`IsCompact.lean`

```
module

public import DomainTheory.DataTypesAsLattices.FixedLattices.WayBelow

def IsCompact {α : Type u} [CompleteLattice α] (x : α) : Prop :=
  WayBelow x x

end DomainTheory.DataTypesAsLattices
```

3.6.8 Continuous basis ✓

A continuous basis assigns to each element a directed family of way-below approximants whose supremum recovers the element.

Definition (`ContinuousBasis`). A map sending each x in a complete lattice to a set $\mathrm{basis}(x)$ is a continuous basis when, for every x: - $\mathrm{basis}(x)$ is directed, - every $y \in \mathrm{basis}(x)$ satisfies $y \ll x$, and - $x = \bigsqcup \mathrm{basis}(x)$.

Proof. These three clauses are the definition of a continuous basis. ■

`ContinuousBasis.lean`

```
module

    (∀ y ∈ basis x, WayBelow y x) ∧
    x = @sSup α completeLatticeSupSet (basis x)

end DomainTheory.DataTypesAsLattices
```

3.6.9 Countably algebraic ✓

A complete lattice is countably algebraic when its compact elements admit a countable enumeration that is dense: every element is the supremum of the compacts below it. Finite-support approximations along that enumeration are directed and recover the same supremum.

Definition (`CountablyAlgebraic`). A complete lattice is countably algebraic when there is an enumeration $n \mapsto c_n$ of compact elements such that every compact equals some c_n, and every x is the supremum of $\{c_n \mid c_n \le x\}$.

Proof. Compactness of each c_n, completeness of the enumeration, and density are the three data of the structure. ■

Definition (`finiteBasisSups`). Given a sequence d and a set x of indices, the finite-basis supremums are the elements $\bigsqcup\{d_n \mid n \in t\}$ for finite $t \subseteq x$.

Proof. Each such supremum is determined by a finite support inside x. ■

Theorem (`finiteBasisSups.sSup_eq`). The supremum of all finite-basis supremums of d along x equals $\bigsqcup\{d_n \mid n \in x\}$.

Proof. Every finite sub-supremum is below the full image supremum; conversely each singleton support is one of the finite-basis supremums. ■

Theorem (`finiteBasisSups.directed`). The set of finite-basis supremums of d along x is directed.

Proof. The empty support supplies a bottom; the union of two finite supports supplies an upper bound. ■

Theorem (`CountablyAlgebraic.compact_finite_support`). If $c_m \le \bigsqcup\{c_n \mid n \in x\}$ in a countably algebraic lattice, then finitely many indices from x already suffice.

Proof. Compactness of c_m against the directed family of finite-basis supremums yields a finite support; the preceding supremum identity rewrites that as a finite sub-image of the enumeration. ■

3.6.10 Representation ✓

The representation of a countably algebraic lattice in $\mathbf{P}\omega$: encode by the set of compact indices below an element, and decode by the supremum of those compacts.

Definition (`representationEncode`). Given a countably algebraic lattice with compact enumeration c_n, the code of an element x is $\{n \in \omega \mid c_n \leq x\}$.

Proof. Membership of an index records that the corresponding compact lies below x. ■

Definition (`representationDecode`). The decode of a set $u \subseteq \omega$ is $\bigsqcup\{c_n \mid n \in u\}$.

Proof. The image of the codes under the enumeration, taken as a supremum. ■

Theorem (`representationDecode.encode`). Decoding the code of x recovers x.

Proof. Every compact below x appears in the code, so density says x is their supremum; conversely each selected compact is already $\leq x$. ■

3.6.11 Closure operation ✓

DEFINITION. An element $a \in \mathbf{P}\omega$ is called a *closure operation* iff it satisfies:

$$\mathbf{I} \subseteq a = a \circ a.$$

We see by definition that a closure operation is not only continuous, but it is also a retract. This is reasonable since the closure of the closure of a subset must be equal to the closure. To say of a function that $\mathbf{I} \subseteq a$ means that $x \subseteq a(x)$ for all $x \in \mathbf{P}\omega$. In other words, every set is contained in its closure. (Note that closures are opposite to the "projections", those retracts where $a \subseteq \mathbf{I}$.) Among examples of closure operations we find $\mathbf{I}$ and $\mathbf{T}$; the first has the most closed sets (fixed points). The second has the least. (Note that $\mathbf{T} = \omega$ always is a fixed point of a closure operation; $\mathbf{T} = \lambda x.\, \mathbf{T}$ is thus the most trivial closure operation.) The examples **fun**, **open**, and **int** of § 4 are all closure operations (cf. (4.1), (4.6), (4.7)). We remarked that **fun** is a retract, but the reader should prove in addition:

$$(5.1) \quad u \subseteq \lambda x.\, u(x),$$

for all $u \in \mathbf{P}\omega$ (cf. Theorem 1.2). We note that this fact can be rewritten in the language of retracts as:

$$(5.2) \quad \mathbf{I} \subseteq \mathbf{I} \circ \to \mathbf{I},$$

the significance of which will emerge after we develop a bit of the theory of closure operations.

Unfortunately the natural definition of the retract **bool** does not yield a closure operation. In this section we adopt this modification:

$$(5.3) \quad \mathbf{boool} = \lambda u.\, u \supset 0,\, \mathbf{T} + 1.$$

The closed sets of **boool** are $\perp$, 0, $\mathbf{T} + 1$, and $\mathbf{T}$. Note that with any closure operation a, the function value $a(x)$ is the least closed set (fixed point of a) including as a subset the given set x. Thus given any family $\mathcal{C} \subseteq \mathbf{P}\omega$ of "closed" sets which is closed under the intersection of subfamilies, if we define

$$(5.4) \quad a(x) = \bigcap \{y \in \mathcal{C} \mid x \subseteq y\},$$

then this will be a closure operation *provided* it is continuous. This remark makes it easy to check that certain functions are closure operations if we can spot easily the family $\mathcal{C}$ of fixed points.

Alas, the "natural" definition of ordered pairs (cf. (2.21)) leads to projections rather than closures. Here we must choose another:

$$(5.5) \quad [x, y] = \{2n \mid n \in x\} \cup \{2m + 1 \mid m \in y\},$$

with these inverse functions:

$$(5.6) \quad [u]_0 = \{n \mid 2n \in u\},$$

$$(5.7) \quad [u]_1 = \{m \mid 2m + 1 \in u\}.$$

We shall find that the main advantage of these equations lies in the obvious equation:

$$(5.8) \quad u = [[u]_0, [u]_1],$$

which is not true for the other pairing functions. Of course we have:

$$(5.9) \quad [[x, y]]_0 = x,$$

$$(5.10) \quad [[x, y]]_1 = y.$$

We shall not extend the idea of these new functions to triples and sequences, though it is clear what to do.

Abstractly, an *algebraic lattice* is a complete lattice in which the isolated points are dense. An *isolated* (sometimes called: *compact*) point in a lattice is one that is not the limit (sup or l.u.b.) of any directed family of its proper subelements. This definition works in continuous lattices, but more generally it is better to say that if the isolated point is *contained in* a sup, then it is also contained in a finite subsup (a sup of a finite selection of elements out of the given sup). In the case of the lattice of subgroups of a group, the isolated ones are the finitely generated subgroups. The isolated points of $\mathbf{P}\omega$ are the finite sets e_n. To say that isolated points are *dense* means that every element in the lattice is the sup of the isolated points it contains. The sequel to Theorem 4.1 for closure operations relates them to algebraic lattices.

Definition (`Closure`). An element $a \in \mathbf{P}\omega$ is a closure operation when $\mathbf{I} \subseteq a$ and a is a retract ($a = a \circ a$).

Proof. Expansiveness $\mathbf{I} \subseteq a$ is $x \subseteq a(x)$ for all x; idempotence is the retract equation. Together these are Scott's display $\mathbf{I} \subseteq a = a \circ a$. ■

3.6.12 Theorem 5.1 — the algebraic lattice theorem ✓

THEOREM 5.1 (The algebraic lattice theorem). *The fixed points of any closure operation form an algebraic lattice.*

Theorem (`theorem_5_1`). The fixed points of any closure operation form an algebraic lattice: their compact elements are the $a(e_n)$, and every fixed point is the directed supremum of the compact fixed points below it.

Proof. A fixed point is compact among the fixed points precisely when it is some $a(e_n)$; the $a(e_n)$ below a given fixed point are directed and recover it as their union. ■

`theorem_5_1.lean`

```
module

end DomainTheory.DataTypesAsLattices
```

3.6.13 Theorem 5.2 — the representation theorem ✓

The proof is very easy if one notes that the isolated points of $\{x \mid x = a(x)\}$, where a is a closure operation, are exactly the images $a(e_n)$ of the finite sets in $\mathbf{P}\omega$. What makes Theorem 5.1 more interesting is the converse.

THEOREM 5.2 (The representation theorem for algebraic lattices). *Every algebraic lattice with a countable number of isolated points is isomorphic to the range of some closure operation.*

By Theorem 1.6 we know that the algebraic lattice is a retract, but a more direct argument makes the closure property clear. Thus, let D be the algebraic lattice with $\{d_n \mid n \in \omega\}$ as the set of all isolated points with the indicated enumeration. We shall use the square notation with symbols $\sqsubseteq$ and $\sqcup$ for the lattice ordering and sup. The desired closure operation is defined by:

$$a(x) = \{m \mid d_m \sqsubseteq \sqcup\{d_n \mid n \in x\}\}.$$

It is an easy exercise to show that from the definition of "isolated" it follows that a is continuous; and from density, it follows that D is in a one-to-one order preserving correspondence with the fixed points of a.

In the last section we introduced an algebra of retracts, much of which carries over to closure operations given the proper definitions. Without any change we can use Theorem 4.3 on function spaces, provided we check that the required retracts are closures.

Theorem (`theorem_5_2`). Every countably algebraic lattice is order-isomorphic to the fixed points of a closure operation on $\mathbf{P}\omega$: the representing map is Scott-continuous, yields a closure, and induces a bijective order correspondence with that closure's fixed points.

Proof. Continuity of the representing map, that it is a closure, and the order isomorphism onto the fixed points. ■

end DomainTheory.DataTypesAsLattices
```

3.6.14 Theorem 5.3 — the function space theorem ✓

THEOREM 5.3 (The function space theorem for algebraic lattices). *Suppose that a and b are closure operations; then so is $a\circ \to b$.*

The proof comes down to showing that

$$u(x) \sqsubseteq b(u(a(x))), \tag{5.11}$$

whenever a and b are closure operations. But this is easy by monotonicity. Note that (5.1) is needed.

For those interested in topology, one can give a construction of the isolated points of the function space which is much more direct than just taking the functions $b \circ e_n \circ a$, which on the face of it do not tell us too much. But we shall not need this explicit construction here.

The reason for changing the pairing functions is to be able to form products and sums of closure operations. In the case of products, the analogue of $\otimes$ is straightforward:

$$a \boxtimes b = \lambda u.\, [a([u]_0), b([u]_1)]; \tag{5.12}$$

while for sums using $a' = \lambda x.\, 0 \cup a(x-1) + 1$ and similarly for b' we write:

$$a \boxplus b = \lambda u.\, ([u]_0 \supset 0,\, 0) \cup ([u]_1 \supset 1,\, 1) \sqsupset [a'([u]_0), \bot],\, [\bot, b'([u]_1)]. \tag{5.13}$$

We can then establish with the aid of (5.8)–(5.10):

Theorem (`theorem_5_3`). If a and b are closure operations, then $a\circ \to b$ is a retract.

Proof. Theorem 4.3(i) already gives idempotence of the function-space retract when a and b are retracts; closures are retracts. ■

Theorem (`theorem_5_3.closure`). If a and b are closure operations, then so is $a\circ \to b$.

Proof. Expansiveness $\mathbf{I} \subseteq a\circ \to b$ together with the preceding retract fact. ■

3.6.15 Theorem 5.4 — the product and sum theorem ✓

THEOREM 5.4 (The product and sum theorem for algebraic lattices). *Suppose that a and b are closure operations; then so are $a \boxtimes b$ and $a \boxplus b$. Analogues of the results in Theorems 4.4 and 4.5 carry over.*

Following the discussion in § 4, we can also show that the closure operations form a Cartesian closed category, which in some ways is better than the category of all retracts. What makes it better is the existence of a "universe".

Every continuous operation generates a closure operation by just closing up the sets under the continuous function (as a set operation). We can institutionalize this thought by means of this definition:

$$(5.14) \quad \mathbf{V} = \lambda a \lambda x.\, \mathbf{Y}(\lambda y.\, x \cup a(y)).$$

Clearly $\mathbf{V}$ is LAMBDA-definable, continuous, etc. A more understandable characterization would define $\mathbf{V}(a)(x)$ by this equation:

$$(5.15) \quad \mathbf{V}(a)(x) = \bigcap \{y \mid x \sqsubseteq y \text{ and } a(y) \sqsubseteq y\}.$$

These two definitions are easily seen to be equivalent. What is unexpected is the discovery (due in a different form to Peter Hancock and Per Martin-Löf) that $\mathbf{V}$ itself is a closure operation.

3.6.16 Theorem 5.5 — the universe theorem ✓

THEOREM 5.5 (The universe theorem for algebraic lattices). *The function* $\mathbf{V}$ *is a closure operation and its fixed points comprise the set of all closure operations.*

Thus to say a is a closure operation, write $a : \mathbf{V}$. To have a mapping on closure operations, write $f : \mathbf{V}\circ \to \mathbf{V}$. Remark that 5.5 allows us to write $\mathbf{V} : \mathbf{V}$. It all seems rather circular, but it is quite consistent. The category of separate algebraic lattices "contains itself"—if we are careful to work through retracts of $\mathbf{P}\omega$.

The proof of Theorem 5.5 requires a few steps. We note first that for all $x, a \in \mathbf{P}\omega$:

$$(5.16) \quad x \subseteq \mathbf{V}(a)(x),$$

Let $y = \mathbf{V}(a)(x)$. This is the least y with $x \cup a(y) \subseteq y$. What is the least z with $y \cup a(z) \subseteq z$? The answer is of course y, which proves:

$$(5.17) \quad \mathbf{V}(a)(\mathbf{V}(a)(x)) = \mathbf{V}(a)(x),$$

Thus $\mathbf{V}(a)$ is always a closure operation. If a is already a closure operation, then clearly $\mathbf{V}(a)(x) = a(x)$. Therefore we have shown:

$$(5.18) \quad a = \mathbf{V}(a) \quad \text{iff} \quad a \text{ is a closure operation.}$$

But then by (5.16) and (5.17) we have by (5.18):

$$(5.19) \quad \mathbf{V}(a) = \mathbf{V}(\mathbf{V}(a)).$$

From (5.16) by monotonicity we see:

$$(5.20) \quad a(x) \subseteq a(\mathbf{V}(a)(x)) \subseteq \mathbf{V}(a)(x).$$

Hence by (5.1) we can derive:

$$(5.21) \quad a \subseteq \lambda x.\, a(x) \subseteq \lambda x.\, \mathbf{V}(a)(x) = \mathbf{V}(a).$$

From (5.19) and (5.21) it follows that $\mathbf{V}$ itself is a closure operation.

The operation $\mathbf{V}$ forms the least closure operation containing a given element, and it shows that the lattice of closure operations is not only a retract of $\mathbf{P}\omega$ but also an algebraic lattice. Since we can now use $\mathbf{V}$ as a retract, the earlier results become formulas:

$$(5.22) \quad (\lambda a : \mathbf{V}.\, \lambda b : \mathbf{V}.\, a \boxtimes b) : \mathbf{V}\circ \to (\mathbf{V}\circ \to \mathbf{V});$$

$$(5.23) \quad (\lambda a : \mathbf{V}.\, \lambda b : \mathbf{V}.\, a \boxplus b) : \mathbf{V}\circ \to (\mathbf{V}\circ \to \mathbf{V});$$

we can also state such functorial properties as:

$$(5.24)\quad (\lambda a : \mathbf{V}.\, \lambda b : \mathbf{V}.\, a\circ \to b) : \mathbf{V}\circ \to (\mathbf{V}\circ \to \mathbf{V}).$$

Using this style of notation we have:

Theorem (`theorem_5_5`). If a is a closure operation, then $\mathbf{V}(a)(x) = a(x)$ for every x, and $\mathbf{V}(a)$ is idempotent: $\mathbf{V}(a)(\mathbf{V}(a)(x)) = \mathbf{V}(a)(x)$.

Proof. The equality with $a(x)$ is (5.18) at a closure; the idempotence is (5.17). ■

3.6.17 Theorem 5.6 — the limit theorem ✓

THEOREM 5.6 (The limit theorem for algebraic lattices).

$$(\lambda f : \mathbf{V}\circ \to \mathbf{V}.\, \mathbf{Y}(f)) : (\mathbf{V}\circ \to \mathbf{V})\circ \to \mathbf{V}.$$

In words: if f is a mapping on closure operations, then its least fixed point is also a closure operation. The proof of course holds with any retract in place of $\mathbf{V}$, but we are more interested in applications to $\mathbf{V}$. For example, note that $\mathbf{V}(\bot) = \mathbf{I}$. Now let $f = \lambda a : \mathbf{V}.\, a\circ \to a$. The least fixed point of this f is the limit of the sequence:

$$\bot,\ \mathbf{I},\ \mathbf{I}\circ \to \mathbf{I},\ (\mathbf{I}\circ \to \mathbf{I})\circ \to (\mathbf{I}\circ \to \mathbf{I}),\ ((\mathbf{I}\circ \to \mathbf{I})\circ \to (\mathbf{I}\circ \to \mathbf{I}))\circ \to ((\mathbf{I}\circ \to \mathbf{I})\circ \to (\mathbf{I}\circ \to \mathbf{I})),\ \ldots$$

and we see that all these retracts are *strict*. This means $\mathbf{Y}(f)$ is nontrivial in that it has at least *two* fixed points (viz., $\bot$ and $\top$). But $d = \mathbf{Y}(f)$ must be the least closure operation satisfying

$$(5.25)\quad d = d\circ \to d,$$

and we have thus proved that there are *nontrivial* algebraic lattices isomorphic to their own function spaces. This construction (which rests on hardly more than (5.2), since we could take $d = \mathbf{Y}(\lambda a.\, \mathbf{I} \cup (a\circ \to a))$) is much quicker than the inverse limit construction originally found by the author to give λ-calculus models satisfying (η). There are many other fixed points of (5.25) besides this least closure operation, but their connection with inverse limits is not fully investigated.

We note in conclusion that most constructions by fixed points give algebraic lattices (like **lamb** in § 4), and so we could just as well do them in $\mathbf{V}$ if we remember to use $\boxtimes$ and $\boxplus$. The one-point space is $\top$ (*not* **nil**), and so the connection with inverse limits via Theorem 4.6 is not as clear when nonstrict functions are used. For many purposes, this may not make any difference.

3.7 Subsets and their classification

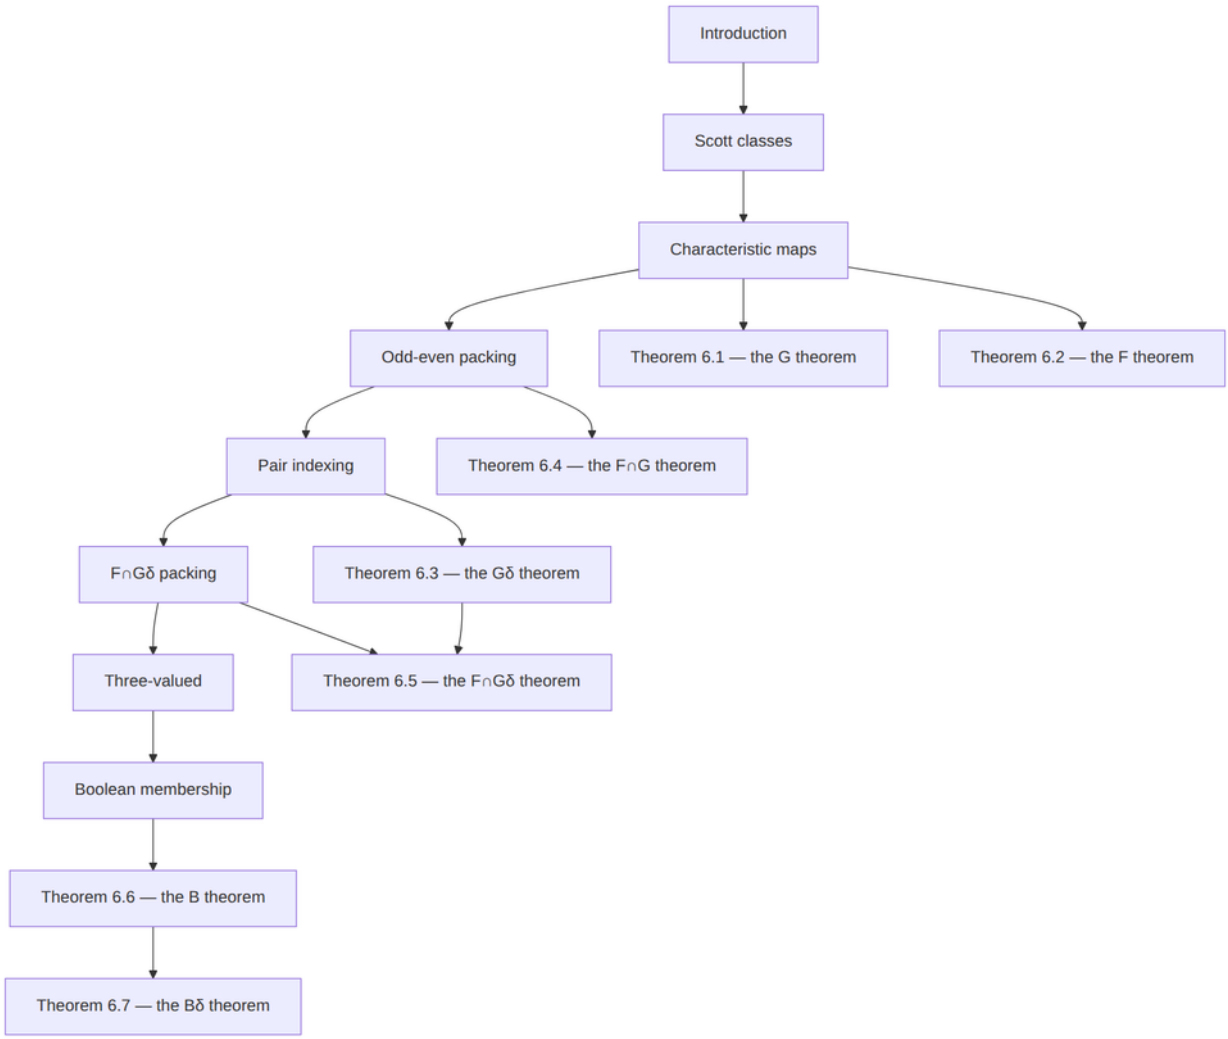

Figure 36: Subsets and their classification.

3.7.1 Introduction ✓

Retracts produce very special subsets of $\mathbf{P}\omega$: a retract always has a nonempty range which forms a lattice under $\sqsubseteq$. For example, the range of **int** is $\{\bot, \top\} \cup \omega$. We often wish to eliminate $\bot$ and $\top$; and with a retract like **tree** the situation is more complex, since combinations like $\langle 1, \langle\langle 1, \langle \bot, \langle 0\rangle\rangle\rangle, \top\rangle\rangle$ might require elimination. In these two cases the method is simple.

Historical note. The classification of these subsets by notions from descriptive set theory, and the connection with Wadge reducibility, are in the work of Adrian Tang. The normal forms for the classes, such as Table 3, are Scott's.

Consider these two functions:

$$(6.1) \quad \mathbf{mid} = \lambda x : \mathbf{int}.\, x \supset 0, 0$$

$$(6.2) \quad \mathbf{perf} = \lambda u : \mathbf{tree}.\, \mathbf{which}(u) \supset 0,\, \Delta(\mathbf{perf}(\mathbf{fst}(\mathbf{out}(u))))(\mathbf{perf}(\mathbf{snd}(\mathbf{out}(u))))$$

where Δ is a special combinator:

$$(6.3) \quad \Delta = \lambda x \lambda y.\, (x \supset (y \supset 0, \top), \top) \cup (y \supset (x \supset 0, \top), \top).$$

We find that $\omega = \{x : \mathbf{int} \mid \mathbf{mid}(x) = 0\}$. In the case of trees, note first this behavior of Δ:

Δ	$\bot$	0	$\top$
$\bot$	$\bot$	$\bot$	$\top$
0	$\bot$	0	$\top$
$\top$	$\top$	$\top$	$\top$

The question is: what subset is $\{u : \mathbf{tree} \mid \mathbf{perf}(u) = 0\}$?
Now **perf** is defined recursively. We can see that

$$\mathbf{perf}(\bot) = \bot, \quad \mathbf{perf}(\top) = \top, \quad \mathbf{perf}(\langle 0 \rangle) = 0,$$

and

$$\mathbf{perf}(\langle 1, \langle x, y \rangle \rangle) = \Delta(\mathbf{perf}(x))(\mathbf{perf}(y))$$

when $x, y : \mathbf{tree}$. Every tree, aside from $\top$ or $\bot$, is either *atomic* or a pair of trees. The atomic tree is "perfect" (that is, $\mathbf{perf}(\langle 0 \rangle) = 0$). A finite tree which does not

contain $\bot$ or $\top$ is perfect—as we can see inductively using the table above for Δ. An infinite tree is never perfect: either some branch ends in $\top$ and **perf** maps it to $\top$, or $\top$ is never reached and **perf** maps it to $\bot$. Thus the subset in question is then seen to be the set of *finite* trees generated from the atom by pairing. This is clearly a desirable subset, and it is sorted out by a function with a simple recursive definition. The general question is: what subsets can be characterized by equations? The answer can be given by reference to the topology of $\mathbf{P}\omega$.

3.7.2 Scott classes ✓

DEFINITION. Let $\mathfrak{G}$ be the class of open subsets of $\mathbf{P}\omega$, and $\mathfrak{F}$ be the class of closed subsets. Further let $\mathfrak{B}$ be the class of all (finite) Boolean combinations of open sets.

We recall from § 1 that $U \in \mathfrak{G}$ just in case for all $x \in \mathbf{P}\omega$, we have $x \in U$ if and only if some finite subset of x is in U. The class of open sets contains $\varnothing$ and $\mathbf{P}\omega$ and is closed under finite intersection and arbitrary union; in fact, it can be generated by these two closure conditions from subsets of the special form $\{x \in \mathbf{P}\omega \mid n \in x\}$ for the various $n \in \omega$. An open set is always *monotonic* (whenever $x \in U$ and $x \subseteq y$, then $y \in U$), so that every nonempty $U \in \mathfrak{G}$ has $\top \in U$.

Another characterization of openness can be given by continuous functions. Suppose $U \in \mathfrak{G}$. Define $f : \mathbf{P}\omega \to \{\bot, \top\}$ so that

$$U = \{x \mid f(x) = \top\};$$

then f is continuous. Conversely, if such an f is continuous, then U is open. But if we do not assume the range of f is included in $\{\bot, \top\}$, this is not true. For the case of general functions we know that f is continuous if and only if $\{x \mid f(x) \in V\}$ is open for all open V. This defines continuity in terms of openness, but we can turn it the other way around:

Definition (`ScottF`). $\mathfrak{F}$ is the class of closed subsets of $\mathbf{P}\omega$: those U whose complement is Scott-open.

Definition (`IsScottGdelta`). U is a $\mathfrak{G}_\delta$ when it is a countable intersection of Scott-open sets.

Definition (`IsFcapG`). U belongs to $\mathfrak{F}\dot{\cap}\mathfrak{G}$ when $U = C \cap O$ for some closed C and Scott-open O.

Definition (`IsFcapGdelta`). U belongs to $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$ when $U = C \cap G$ for some closed C and $\mathfrak{G}_\delta$ set G.

Definition (`IsBooleanOpen`). The Boolean combinations of Scott-open sets are generated inductively by taking opens, binary unions, binary intersections, and complements.

Definition (`ScottB`). $\mathfrak{B}$ is the class of sets satisfying $\mathrm{IsBooleanOpen}$.

Definition (`IsBdelta`). U is a $\mathfrak{B}_\delta$ when it is a countable intersection of Boolean combinations of opens.

Theorem (`IsBooleanOpen.of_closed`). Every closed set is Boolean.

Proof. The complement of a closed set is open, hence Boolean, and Boolean sets are closed under complement. ■

Theorem (`IsBooleanOpen.of_fcapG`). Every set in $\mathfrak{F}\dot{\cap}\mathfrak{G}$ is Boolean.

Proof. Intersect a closed (hence Boolean) set with an open. ■

Theorem (`IsBooleanOpen.sUnion_finite`). A finite union of Boolean sets is Boolean.

Proof. By induction on the finite family: the empty union is the empty open set, and binary union closes the inductive step. ■

3.7.3 Characteristic maps ✓

Characteristic maps detect membership in Scott-open or closed sets by continuous equations with the numerals 0, $\bot$, and $\top$.

Definition (`charOpen`). $\mathrm{charOpen}\, U\, x = \{k \mid k = 0 \wedge \exists n.\, e_n \subseteq x \wedge e_n \in U\}$.

Definition (`charTop`). $\mathrm{charTop}\, U\, x = \{k \mid \exists n.\, e_n \subseteq x \wedge e_n \in U\}$.

Definition (`closedToZero`). $\mathrm{closedToZero}\, C\, x = 0 \cup \mathrm{charTop}\, C^{\mathrm{c}}\, x$.

Theorem (`charOpen.isScottContinuous`). For every U, the map $x \mapsto \mathrm{charOpen}\, U\, x$ is Scott-continuous.

Proof. Membership of a coordinate at x is witnessed by a finite $e_n \subseteq x$ and reassembles under Scott unions. ■

Theorem (`charOpen.eq_zero`). If U is Scott-open, then $\mathrm{charOpen}\, U\, x = 0$ if and only if $x \in U$.

Proof. A witness $e_n \subseteq x$ in U and upward closure put x in U; conversely Scott-open membership supplies such a witness, forcing the value to equal the numeral 0. ■

Theorem (`charOpen.threeValued`). Every value of $\mathrm{charOpen}\, U$ is three-valued (in fact $\bot$ or 0).

Proof. Either 0 belongs to the value, which forces equality with the numeral 0, or the value is empty. ■

Theorem (`charTop.isScottContinuous`). For every U, the map $x \mapsto \mathrm{charTop}\, U\, x$ is Scott-continuous.

Proof. Finite witnesses of membership assemble under Scott unions, as for $\mathrm{charOpen}$. ■

Theorem (`charTop.eq_top`). If U is Scott-open, then $\mathrm{charTop}\, U\, x = \top$ if and only if $x \in U$.

Proof. Membership of 0 in a top value yields a finite witness in U; conversely Scott-openness supplies a witness for every coordinate of $\top$. ■

Theorem (`charTop.eq_bot`). If U is Scott-open, then $\mathrm{charTop}\, U\, x = \bot$ if and only if $x \notin U$.

Proof. Compare with the previous equivalence and the emptiness of $\bot$. ■

Theorem (`charTop.eq_bot_of_closed`). If C^{c} is Scott-open, then $\mathrm{charTop}\, C^{\mathrm{c}}\, x = \bot$ if and only if $x \in C$.

Proof. Apply the previous equivalence to the complement. ■

Theorem (`closedToZero.isScottContinuous`). For every C, the map $x \mapsto \mathrm{closedToZero}\, C\, x$ is Scott-continuous.

Proof. It is the pointwise union of a constant numeral with $\mathrm{charTop}\, C^{\mathrm{c}}$, and binary union is Scott-continuous in each argument separately. ■

Theorem (`closedToZero.threeValued`). If C^{c} is Scott-open, every value of $\mathrm{closedToZero}\, C$ is three-valued.

Proof. On C the characteristic of the complement is $\bot$, so the union equals 0; off C it is $\top$, so the union equals $\top$. ■

Theorem (`closedToZero.eq_zero`). If C^{c} is Scott-open, then $\mathrm{closedToZero}\, C\, x = 0$ if and only if $x \in C$.

Proof. Off C the value is $\top$, distinct from 0; on C it collapses to 0. ■

3.7.4 Odd-even packing ✓

Odd–even packing interlaces two maps on the odd and even numerals and recovers each factor by parity projection.

Definition (`oddPart`). $\mathrm{oddPart}\, y = \{n \mid 2n+1 \in y\}$.

Definition (`evenPart`). $\mathrm{evenPart}\, y = \{n \mid 2n \in y\}$.

Definition (`oddEvenPack`).

$$(\mathrm{oddEvenPack}\, f\, g)\, x = \{k \mid (\exists n.\, k = 2n+1 \wedge n \in f(x)) \vee (\exists n.\, k = 2n \wedge n \in g(x))\}.$$

Theorem (`oddEvenPack.eq_zero`). $\mathrm{oddEvenPack}\ f\ g\ x = 0$ if and only if $f(x) = \bot$ and $g(x) = 0$.

Proof. An odd packed index forces $f(x)$ empty; an even packed index forces $g(x)$ to be the singleton $\{0\}$; the converse packs those values back to the numeral 0. ■

Theorem (`oddEvenPack.isScottContinuous`). If f and g are Scott-continuous, so is $\mathrm{oddEvenPack}\ f\ g$.

Proof. Each parity clause pulls a Scott-union witness from f or g and pushes it forward; monotonicity of f and g closes the converse. ■

Theorem (`oddEvenPack.evenPart`). $\mathrm{evenPart}(\mathrm{oddEvenPack}\ f\ g\ x) = g(x)$.

Proof. Even indices unpack exactly the members of $g(x)$; odd indices cannot contribute. ■

Theorem (`oddEvenPack.oddPart`). $\mathrm{oddPart}(\mathrm{oddEvenPack}\ f\ g\ x) = f(x)$.

Proof. Symmetric to the even case. ■

Theorem (`oddEvenPack.subset`). If $f(x) \subseteq \{m \mid m < N\}$ and $g(x) \subseteq \{m \mid m < M\}$, then $\mathrm{oddEvenPack}\ f\ g\ x \subseteq \{k \mid k < 2\max(N, M) + 1\}$.

Proof. An odd or even packed index is strictly less than twice the corresponding bound, plus one on the odd side. ■

3.7.5 Pair indexing ✓

Pair indexing packs a sequence of maps into one map via Cantor pairing of fibre indices with values.

Definition (`pairIndexed`).

$$(\mathrm{pairIndexed}\, f_s)\, x = \{k \mid \exists n\, m.\, k = \langle n, m\rangle \wedge m \in f_s(n)(x)\}.$$

Theorem (`pairIndexed.eq_top`). $\mathrm{pairIndexed}\, f_s\, x = \top$ if and only if every $f_s(n)(x)$ equals $\top$.

Proof. Every pair code belongs to the packed value precisely when each fibre is universal; surjectivity of pairing recovers the fibres. ■

Theorem (`pairIndexed.isScottContinuous`). If each $f_s(n)$ is Scott-continuous, so is pairIndexed f_s.

Proof. Membership of a pair code pulls a Scott-union witness from the corresponding fibre and reassembles under the packed Scott union; monotonicity of each fibre closes the converse. ■

3.7.6 F∩Gδ packing ✓

The $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$ packing combines a map that detects a closed fibre with one that detects a $\mathfrak{G}_\delta$ fibre, encoding the closed side at 0 and the open sequence on positive numerals.

Definition (`fcapGdeltaPack`).

$$(\mathrm{fcapGdeltaPack}\, f\, g)\, x = \{k \mid (k = 0 \wedge 0 \in f(x)) \vee (\exists n.\, k = n + 1 \wedge n \in g(x))\}.$$

Theorem (`fcapGdeltaPack.isScottContinuous`). If f and g are Scott-continuous, so is $\mathrm{fcapGdeltaPack}\, f\, g$.

Proof. The clause $0 \in f(x)$ and each clause $n \in g(x)$ pull Scott-union witnesses from f or g; monotonicity of f and g closes the converse. ■

Theorem (`fcapGdeltaPack.eq`). Suppose $f(x)$ is $\bot$ or $\top$. Then $\mathrm{fcapGdeltaPack}\, f\, g\, x = \mathrm{succSet}\, \top$ if and only if $f(x) = \bot$ and $g(x) = \top$.

Proof. The successor of $\top$ never contains 0, so a packed value equal to $\mathrm{succSet}\, \top$ forces $0 \notin f(x)$, hence $f(x) = \bot$ under the two-point hypothesis, while positive packed indices force $g(x) = \top$. Conversely, with $f(x) = \bot$ and $g(x) = \top$ the packed value is exactly the positive numerals. ■

3.7.7 Three-valued ✓

Three-valued elements of $\mathbf{P}\omega$ are $\bot$, the numeral 0, and $\top$. The auxiliary maps uvU and uvV agree on three-valued arguments precisely when at least one argument is 0.

Definition (`ThreeValued`). An element is three-valued when it equals $\bot$, 0, or $\top$.

Definition (`zeroPrime`). $\mathrm{zeroPrime} = 0 \cup 1$.

Definition (`uvU`, `uvV`). Two continuous binary combinations of arguments used to detect equalizers among three-valued values (Scott's U and V tables).

Theorem (`zeroPrime.ne_ofNat_zero`). $\mathrm{zeroPrime} \neq 0$.

Proof. $1 \in \mathrm{zeroPrime}$ but $1 \notin 0$. ■

Theorem (`zeroPrime.ne_top`). $\mathrm{zeroPrime} \neq \top$.

Proof. $2 \notin \mathrm{zeroPrime}$. ■

Theorem (`uvU.mono_left`, `uvU.mono_right`, `uvV.mono_left`, `uvV.mono_right`). Each of uvU and uvV is monotone in each argument separately.

Proof. Enlarging an argument only adds positive membership witnesses used by the clauses. ■

Theorem (`uvU.isScottContinuous_left`, `uvU.isScottContinuous_right`, `uvV.isScottContinuous_left`, `uvV.isScottContinuous_right`). Fixing either argument, both maps are Scott-continuous in the other.

Proof. Each clause that places 0 or 1 in the value is witnessed by a finite e_n from the varying argument; Scott unions reassemble those witnesses, and monotonicity closes the converse. ■

Theorem (`uvU.bot_bot`, `uvU.bot_zero`, `uvU.zero_bot`, `uvU.zero_zero`, `uvU.bot_top`, `uvU.top_bot`, `uvU.zero_top`, `uvU.top_zero`, `uvU.top_top`). The nine three-valued evaluations of uvU match Scott's U-table.

Proof. Direct case analysis on membership of 0 and of positive numerals in $\bot$, 0, and $\top$. ■

Theorem (`uvV.bot_bot`, `uvV.bot_zero`, `uvV.zero_bot`, `uvV.zero_zero`, `uvV.bot_top`, `uvV.top_bot`, `uvV.zero_top`, `uvV.top_zero`, `uvV.top_top`). The nine three-valued evaluations of uvV match Scott's V-table.

Proof. The same case analysis for the clauses defining uvV. ■

Theorem (`ThreeValued.uvU_eq_uvV`). If x and y are three-valued, then $\mathrm{uvU}\,x\,y = \mathrm{uvV}\,x\,y$ if and only if $x = 0$ or $y = 0$.

Proof. Evaluate the nine cases against the tables and the inequalities among $\bot$, 0, $\mathrm{zeroPrime}$, and $\top$. ■

3.7.8 Boolean membership ✓

Boolean membership packages a Scott-continuous map of uniformly bounded values together with a finite set of admissible values inside that bound; the class contains every Scott-open set and is closed under the Boolean operations.

Definition (`BooleanMemE`). A set U has Boolean membership when there exist a Scott-continuous f, a bound N, and a finite set E of subsets of $\{m \mid m < N\}$ such that $f(x) \subseteq \{m \mid m < N\}$ for every x and $U = \{x \mid f(x) \in E\}$.

Theorem (`BooleanMemE.finite_Iio`). Every initial segment $\{m \mid m < N\}$ of ω is finite.

Proof. It coincides with the finite set $\{0, \ldots, N-1\}$. ■

Theorem (`BooleanMemE.finite_subsets_lt`). The set of subsets of $\{m \mid m < N\}$ is finite.

Proof. The powerset of a finite set is finite. ■

Theorem (`BooleanMemE.ofOpen`). Every Scott-open set has Boolean membership.

Proof. Take $f = \mathrm{charOpen}\, U$, bound 1, and $E = \{0\}$. Continuity of the characteristic map is already known; Scott-open membership supplies a finite witness forcing $\mathrm{charOpen}\, U\, x = 0$, and conversely a zero value yields a witness in U. ■

Theorem (`BooleanMemE.union`). Boolean membership is closed under binary unions.

Proof. Odd–even pack the two witnessing maps with bound $2\max(N, M) + 1$, and admit those packed values whose odd part lies in the first admissible set or whose even part lies in the second; the parity

projections recover membership in either factor. ■

Theorem (`BooleanMemE.inter`). Boolean membership is closed under binary intersections.

Proof. The same packing and bound, now requiring both parity projections to land in the respective admissible sets. ■

Theorem (`BooleanMemE.compl`). Boolean membership is closed under complements.

Proof. Keep the same continuous map and bound, and replace the admissible set by its relative complement inside the finite powerset of $\{m \mid m < N\}$. ■

3.7.9 Theorem 6.1 — the G theorem ✓

THEOREM 6.1 (The $\mathfrak{G}$ theorem). *The open subsets of* $\mathbf{P}\omega$ *are exactly the sets of the form:*

$$\{x \mid f(x) \supseteq 0\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ *is continuous.*

We could have written $0 \in f(x)$ or the equation $f(x) \cap 0 = 0$ instead of $f(x) \supseteq 0$. Note that in case $f : \mathbf{P}\omega \to \{\bot, \top\}$, then $f(x) \supseteq 0$ is equivalent to $f(x) = \top$. Also any other integer could have been used in place of 0.

We can say that $\{x \mid 0 \in x\}$ is the *typical* open set, and that every other open set can be obtained as an inverse image of the typical set by a continuous function. We shall extend this pattern to other classes, especially looking for equations. In the case of openness an inequality could also be used, giving as the typical set $\{x \mid x \neq \bot\}$. But since closed sets are just the complements of open sets, this remark gives us:

Theorem (`theorem_6_1`). A subset $U \subseteq \mathbf{P}\omega$ is Scott-open if and only if $U = \{x \mid 0 \in f(x)\}$ for some Scott-continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. If f is Scott-continuous, then $0 \in f(x)$ holds exactly when some finite $e_n \subseteq x$ already satisfies $0 \in f(e_n)$, so the fibre is a union of basic Scott neighbourhoods. Conversely, the characteristic map $\mathrm{charOpen}\, U$ is Scott-continuous and equals the numeral 0 precisely on U, so membership of 0 recovers U. ■

3.7.10 Theorem 6.2 — the F theorem ✓

THEOREM 6.2 (The $\mathfrak{F}$ theorem). *The closed subsets of* $\mathbf{P}\omega$ *are exactly the sets of the form:*

$$\{x \mid f(x) = \bot\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ *is continuous.*

Aside from $\{x \mid x = \bot\}$, we could have used $\{x \mid x \subseteq a\}$ as the typical closed set where $a \in \mathbf{P}\omega$ is any element whatsoever aside from $\top$. This $\top$ has, by the way, a

special character. We note:

$$\{\top\} = \bigcap\{\{x \mid n \in x\} \mid n \in \omega\}.$$

Thus $\{\top\}$ is a countable intersection of open sets, otherwise called a $\mathfrak{G}_\delta$-set. There are of course many other $\mathfrak{G}_\delta$-sets, but $\{\top\}$ is the typical one:

Theorem (`theorem_6_2`). A subset $U \subseteq \mathbf{P}\omega$ is Scott-closed if and only if $U = \{x \mid f(x) = \bot\}$ for some Scott-continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. If U is closed, then $\mathrm{charTop}\, U^{\mathrm{c}}$ is Scott-continuous and equals $\bot$ precisely on U. Conversely, if f is Scott-continuous then the complement of $\{x \mid f(x) = \bot\}$ is the union over k of the open fibres $\{x \mid k \in f(x)\}$, hence open, so the fibre of $\bot$ is closed. ■

3.7.11 Theorem 6.3 — the Gδ theorem ✓

THEOREM 6.3 (The $\mathfrak{G}_\delta$ theorem). *The countable intersections of open subsets of $\mathbf{P}\omega$ are exactly the sets of the form:*

$$\{x \mid f(x) = \top\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is continuous.

It may not be obvious that every $\mathfrak{G}_\delta$-set has this form. Certainly, as we have remarked, every $\mathfrak{G}$-set has this form. Thus if W is a $\mathfrak{G}_\delta$, we have:

$$W = \bigcap\{U_n \mid n \in \omega\},$$

and further,

$$U_n = \{x \mid f_n(x) = \top\},$$

where the f_n are suitably chosen continuous functions. Define the function g by the equation:

$$g(x) = \{(n, m) \mid m \in f_n(x)\}.$$

Clearly g is continuous, and we have:

$$W = \{x \mid g(x) = \top\},$$

as desired.

We let $\mathfrak{F}\dot{\cap}\mathfrak{G}$ denote the class of all sets of the form $C \cap U$, where $C \in \mathfrak{F}$ and $U \in \mathfrak{G}$. Similarly for $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$. Now $\{x \mid x \subseteq 0\}$ is closed and $\{x \mid x \supseteq 0\}$ is open. Thus $\{0\} \in \mathfrak{F}\dot{\cap}\mathfrak{G}$. This set is typical.

Theorem (`theorem_6_3`). A subset $U \subseteq \mathbf{P}\omega$ is a $\mathfrak{G}_\delta$ if and only if $U = \{x \mid f(x) = \top\}$ for some Scott-continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. If $U = \bigcap_n U_n$ with each U_n Scott-open, pair-index the maps $\mathrm{charTop}\, U_n$; the packed value is $\top$ precisely when every factor is $\top$, hence precisely on the intersection. Conversely, if f is Scott-continuous then $\{x \mid f(x) = \top\}$ is the intersection over n of the open fibres $\{x \mid n \in f(x)\}$. ■

3.7.12 Theorem 6.4 — the F∩G theorem ✓

THEOREM 6.4 (The $\mathfrak{F}\dot{\cap}\mathfrak{G}$ theorem). *The sets that are intersections of closed sets with open sets are exactly the sets of the form:*

$$\{x \mid f(x) = 0\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is continuous.

Again it may not be obvious that every $\mathfrak{F}\dot{\cap}\mathfrak{G}$ set has this form. We can write:

$$C = \{x \mid f(x) = \bot\},$$

and

$$U = \{x \mid g(x) = 0\},$$

where $C \in \mathfrak{F}$ and $U \in \mathfrak{G}$ and the continuous f and g are suitably chosen. Define

$$h(x) = \{2n+1 \mid n \in f(x)\} \cup \{2n \mid n \in g(x)\},$$

and remark that h is continuous. We have:

$$C \cap U = \{x \mid h(x) = 0\},$$

as desired.

It is easy to see that $\{e\} \in \mathfrak{F}\dot{\cap}\mathfrak{G}$ if e is finite, but in general $\{a\} \notin \mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$. In

In case a is infinite but not equal to $\top$ (say, $a = \{n \mid n > 0\} = \top + 1$), then $\{a\}$ is typical in its class.

Theorem (`theorem_6_4`). A subset $U \subseteq \mathbf{P}\omega$ belongs to $\mathfrak{F}\dot{\cap}\mathfrak{G}$ if and only if $U = \{x \mid f(x) = 0\}$ for some Scott-continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. If $U = C \cap O$ with C closed and O open, odd–even pack $\mathrm{charTop}\, C^{\mathrm{c}}$ with $\mathrm{charOpen}\, O$; the packed value equals the numeral 0 precisely when the closed factor is $\bot$ and the open factor is 0. Conversely, if f is Scott-continuous then $\{x \mid f(x) = 0\}$ is the intersection of the closed set $\{x \mid f(x) \subseteq 0\}$ with the open fibre $\{x \mid 0 \in f(x)\}$. ■

3.7.13 Theorem 6.5 — the F∩Gδ theorem ✓

THEOREM 6.5 (The $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$ theorem). *The sets that are intersections of closed sets with countable intersections of open sets are exactly the sets of the form:*

$$\{x \mid f(x) = a\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is continuous and a is a fixed infinite set not equal to $\top$.

Note that $(\mathfrak{F}\dot{\cap}\mathfrak{G})_\delta$ is the same class as $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$, so we see by Theorem 6.4 that a good choice of a is $\lambda n \in \omega.0$.

There is no single subset of $\mathbf{P}\omega$ typical for $\mathfrak{B}$, which can be viewed as the finite unions of sets from the class $\mathfrak{F}\dot{\cap}\mathfrak{G}$.

Theorem (`theorem_6_5`). A subset $U \subseteq \mathbf{P}\omega$ belongs to $\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$ if and only if $U = \{x \mid f(x) = \mathrm{succSet}\ \top\}$ for some Scott-continuous $f : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. If $U = C \cap G$ with C closed and G a $\mathfrak{G}_\delta$, take a continuous fibre of $\top$ for G by Theorem 6.3 and pack it with $\mathrm{charTop}\, C^{\mathrm{c}}$; the packed value equals $\mathrm{succSet}\ \top$ precisely when the closed factor is $\bot$ and the $\mathfrak{G}_\delta$ factor is $\top$. Conversely, if f is Scott-continuous then $\{x \mid f(x) = \mathrm{succSet}\ \top\}$ is the intersection of the closed set $\{x \mid f(x) \subseteq \mathrm{succSet}\ \top\}$ with the $\mathfrak{G}_\delta$ set $\{x \mid \mathrm{succSet}\ \top \subseteq f(x)\}$. ■

3.7.14 Theorem 6.6 — the B theorem ✓

THEOREM 6.6 (The $\mathfrak{B}$ theorem). *The sets that are Boolean combinations of open sets are exactly the sets of the form:*

$$\{x \mid f(x) \in \mathcal{E}\},$$

where $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is continuous and $\mathcal{E}$ is a finite set of finite elements of $\mathbf{P}\omega$.

To see that every $\mathfrak{B}$ set has this form, suppose that

$$V = W_0 \cup W_1 \cup \cdots \cup W_{n-1},$$

where each $W_i \in \mathfrak{F}\dot{\cap}\mathfrak{G}$. We can write:

$$W_i = \{x \mid f_i(x) = 0\},$$

where $f_i : \mathbf{P}\omega \to \{\bot, 0, \top\}$ is continuous. Then define:

$$g(x) = \{2i + j \mid j \in f_i(x) \cap \{0, 1\}, i < n\},$$

and note that g is continuous. Let

$$\mathcal{E} = \{y \subseteq \{m \mid m < 2n\} \mid \exists i < n.2i \in y, 2i + 1 \notin y\};$$

we have:

$$V = \{x \mid g(x) \in \mathcal{E}\}$$

as desired.

Theorem (`theorem_6_6`). A subset $U \subseteq \mathbf{P}\omega$ is a Boolean combination of Scott-open sets if and only if $U = \{x \mid f(x) \in E\}$ for some Scott-continuous f and some finite set E of finite elements of $\mathbf{P}\omega$.

Proof. Boolean membership yields a continuous map of uniformly bounded values with a finite admissible set of subsets of that bound, each of which is finite. Conversely, each fibre $\{x \mid f(x) = e\}$ for finite e is an $\mathfrak{F}\dot{\cap}\mathfrak{G}$ set (closed upper and open lower sandwich), hence Boolean, and a finite union of those fibres recovers $\{x \mid f(x) \in E\}$. ■

3.7.15 Theorem 6.7 — the Bδ theorem ✓

THEOREM 6.7 (The $\mathfrak{B}_\delta$ theorem). *The sets that are countable intersections of Boolean combinations of open sets are exactly the sets of the form:*

$$\{x \mid f(x) = g(x)\},$$

where $f, g : \mathbf{P}\omega \to \mathbf{P}\omega$ are continuous.

This is clearly the most interesting of these characterization theorems, because equations like $f(x) = g(x)$ turn up all the time and the collection is a very rich totality of subsets of $\mathbf{P}\omega$. It includes all the retracts, since they are of the form $\{x \mid x = a(x)\}$. And much more. That every such set in Theorem 6.7 is $\mathfrak{B}_\delta$ follows from these logical transformations:

$$\{x \mid f(x) = g(x)\} = \{x \mid \forall n \in \omega[n \in f(x) \leftrightarrow n \in g(x)]\}$$

$$= \bigcap_{n=0}^{\infty} (\{x \mid n \in f(x), n \in g(x)\} \cup \{x \mid n \notin f(x), n \notin g(x)\})$$

That puts the set in the class $(\mathfrak{F} \cup \mathfrak{G})_\delta = \mathfrak{B}_\delta$.

On the other hand, we can see that $(\mathfrak{F} \cup \mathfrak{G})_\sigma$ is exactly $\mathfrak{B}_\delta$. Because, in view of Theorem 6.6, $\mathfrak{B}_\sigma$, the class of *countable* unions of $\mathfrak{B}$-sets, is exactly $(\mathfrak{F} \dot{\cap} \mathfrak{G})_\sigma$. The remark we want to make then follows by taking complements.

Now let S be an arbitrary $\mathfrak{B}_\delta$-set. We can write:

$$S = \bigcap_{n=0}^{\infty} (\{x \mid f_n(x) = 0\} \cup \{x \mid g_n(x) = 0\}),$$

where $f_n, g_n : \mathbf{P}\omega \to \{\bot, 0, \top\}$ are continuous. Now let u, v be continuous functions which on $\{\bot, 0, \top\}$ realize these two tables:

u	$\bot$	0	$\top$
$\bot$	$\bot$	0	0
0	0	0	$0'$
$\top$	0	$0'$	$0'$

v	$\bot$	0	$\top$
$\bot$	0	0	$0'$
0	0	0	$0'$
$\top$	$0'$	$0'$	$\top$

where $0' = 0 \cup \bot$. This is an exercise in many-valued logic, and we find for $x, y \in \{\bot, 0, \top\}$:

$$u(x)(y) = v(x)(y) \quad \text{iff} \quad x = 0 \text{ or } y = 0.$$

Thus define continuous functions f' and g' such

$$f' = \lambda x \lambda n \in \omega . u(f_n(x))(g_n(x)),$$
$$g' = \lambda x \lambda n \in \omega . v(f_n(x))(g_n(x)),$$

and we find:

$$S = \{x \mid f'(x) = g'(x)\}$$

as desired.

This is as far as we can go with *equations*. More complicated sets can be defined using *quantifiers*, for example the Σ^1_1 or *analytic* sets can be put in the form:

$$\{x \mid \exists y . f(x)(y) = g(x)(y)\},$$

and their complements, the Π^1_1 sets, in the form

$$\{x \mid \forall y \exists z . h(x)(y)(z) = 0\},$$

with continuous f, g, h. For the three classes we then have as "typical" sets those shown in Table 3.

It should be remarked that $\mathfrak{B}_\delta$ contains all the closed sets in the *Cantor space* topology on $\mathbf{P}\omega$ (that is, the topology obtained when it is regarded as the infinite product of *discrete* two-point spaces). Therefore the Σ^1_1 sets for the two topologies on $\mathbf{P}\omega$ are the *same*. Hence, since we know for Cantor space that $\Delta^1_1 = \Sigma^1_1 \cap \Pi^1_1$ is the class of *Borel sets*, we can conclude that the two topologies on $\mathbf{P}\omega$ have the *same* Borel sets. (That is, in both cases Δ^1_1 is the Boolean σ-algebra generated from the open sets.)

TABLE 3 *Classes and typical sets*

Classes	Typical sets
$\mathfrak{G}$	$\{x \mid 0 \in x\}$
$\mathfrak{F}$	$\{\bot\}$

Classes	Typical sets
$\mathfrak{G}_\delta$	$\{\top\}$
$\mathfrak{F}\dot{\cap}\mathfrak{G}$	$\{0\}$
$\mathfrak{F}\dot{\cap}\mathfrak{G}_\delta$	$\{\top + 1\}$
$\mathfrak{B}_\delta$	$\{u \mid u_0 = u_1\}$
Σ^1_1	$\{u \mid \exists y.\, u_0(y) = u_1(y)\}$
Π^1_1	$\{u \mid \forall y \exists z.\, u(y)(z) = 0\}$

Returning now to the example involving trees mentioned at the beginning of this section, we see that the set of perfect (finite) trees can be written in the form:

$$\{x \mid x = \mathbf{tree}(x),\, \mathbf{perf}(x) = 0\} = \{x \mid \langle x,\, \mathbf{perf}(x)\rangle = \langle \mathbf{tree}(x),\, 0\rangle\};$$

thus it is a $\mathfrak{B}_\delta$-set. (Note that $\mathfrak{B}_\delta$ are obviously closed under finite intersection by the ordered pair method just illustrated; that they are closed under finite union is a little messier to make explicit, but the essential idea is contained in the proof of Theorem 6.7.)

As another example, we might wish to allow infinite trees but not the strange tree $\top$. Consider the following function:

$$(6.4) \quad \mathbf{top} = \lambda u : \mathbf{tree}.\, \mathbf{which}(u) \sqsubseteq \bot,\, \mathbf{top}(\mathbf{fst}(\mathbf{out}(u))) \cup \mathbf{top}(\mathbf{snd}(\mathbf{out}(u))).$$

We can show that $\mathbf{top} : \mathbf{P}\omega \to \{\bot, \top\}$. For a tree u the equation $\mathbf{top}(u) = \bot$ means that it *does not* contain $\top$, or as we might say: it is *topless*. The topless trees form a closed subset of the subspace of trees. (An interesting retract is the function $\lambda u.\, \mathbf{tree}(u) \cup \mathbf{top}(u)$ whose range consists exactly of the topless trees plus *one* exceptional tree $\top$.) Such a closed subset of (the range of) a retract is a kind of *semilattice*. (We shall not introduce a precise definition here.) Every directed subset has a limit (least upper bound) and every pair with an upper bound has a least upper bound. But generally least upper bounds do not have to exist within the semilattice. The type of domains that interest us *become* continuous lattices with the *addition* of a top element $\top$ larger than all the other elements. The elimination of $\top$ is done with a function like $\mathbf{top}$ of our example. This is convincing evidence to the author that an independent theory of semilattices is quite unnecessary: they can all be *derived* from lattices. The problem is simply to define the top-cutting operation, then restriction to the "topless" elements is indicated by an equation (like $\mathbf{top}(u) = \bot$). In this way all the constructions are kept within the control of a smooth-running theory based on **LAMBDA**. This point seems to be important if one wants to keep track of which functions are computable.

An aspect of the problem of classification treated in this section which has not been given close enough attention is the explicitly constructive way of verifying the closure properties of the classes. Consider the class $\mathfrak{B}_\delta$, for example. Let B be the typical set as shown in Table 3. Then whatever $f \in \mathbf{P}\omega$ we choose, the set

$$\{x \mid f(x) \in B\}$$

is a $\mathfrak{B}_\delta$-set and every such set has this form. Thus the f's *index* the elements of the class. Suppose $f, g \in \mathbf{P}\omega$. What we should look for are two LAMBDA-definable combinators such that $\mathbf{union}(f)(g)$ and $\mathbf{inter}(f)(g)$ give the functions that index the union and intersection of the sets determined by f and g. That is, we want:

$$\{x \mid \mathbf{union}(f)(g)(x) \in B\} = \{x \mid f(x) \in B\} \cup \{x \mid g(x) \in B\}.$$

It should be possible to extract the precise definition from the outline of the proofs given above, but in general this matter needs more investigation. There may very well be certain classes where such operations are not constructive, even though the classes are simply defined.

Theorem (`theorem_6_7.of_equalizer`). Every equalizer $\{x \mid f(x) = g(x)\}$ of Scott-continuous maps is a $\mathfrak{B}_\delta$.

Proof. For each n, the set where n belongs to both values or to neither is a Boolean combination of open fibres; the equalizer is their countable intersection. ■

Theorem (`theorem_6_7.iInter_equalizer`). A countable family of continuous equalizers $\{x \mid \forall n.\, f_n(x) = g_n(x)\}$ is itself a single equalizer of continuous maps.

Proof. Pair-index the two sequences; the packed values agree precisely when every fibre agrees. ■

Theorem (`theorem_6_7.converse_of_equalizers`). If $U = \{x \mid \forall n.\, f_n(x) = g_n(x)\}$ for continuous f_n, g_n, then U is an equalizer of two continuous maps.

Proof. Apply the previous packing. ■

Theorem (`theorem_6_7.boolean_as_iInter_open_union_closed`). Every Boolean combination of opens is a countable intersection of sets of the form $O_n \cup C_n$ with O_n open and C_n closed.

Proof. By Theorem 6.6 the complement is a continuous fibre of a finite set E of finite values; induct on E, slicing each finite value as the intersection of an open upper set and a closed lower set, and reindexing the accumulating intersection. ■

Theorem (`theorem_6_7.of_bdelta`). Every $\mathfrak{B}_\delta$ is an equalizer of two Scott-continuous maps.

Proof. Expand each Boolean factor by the previous theorem, reindex the double sequence by pairing, pack open and closed characteristics with the three-valued tables U and V so that equalizers of the packed sequence recover the intersection, and collapse that sequence of equalizers to one equation. ■

Theorem (`theorem_6_7`). A subset $U \subseteq \mathbf{P}\omega$ is a $\mathfrak{B}_\delta$ if and only if $U = \{x \mid f(x) = g(x)\}$ for some Scott-continuous $f, g : \mathbf{P}\omega \to \mathbf{P}\omega$.

Proof. The two directions are the equalizer and $\mathfrak{B}_\delta$ tools above. ■

3.8 Total functions and functionality

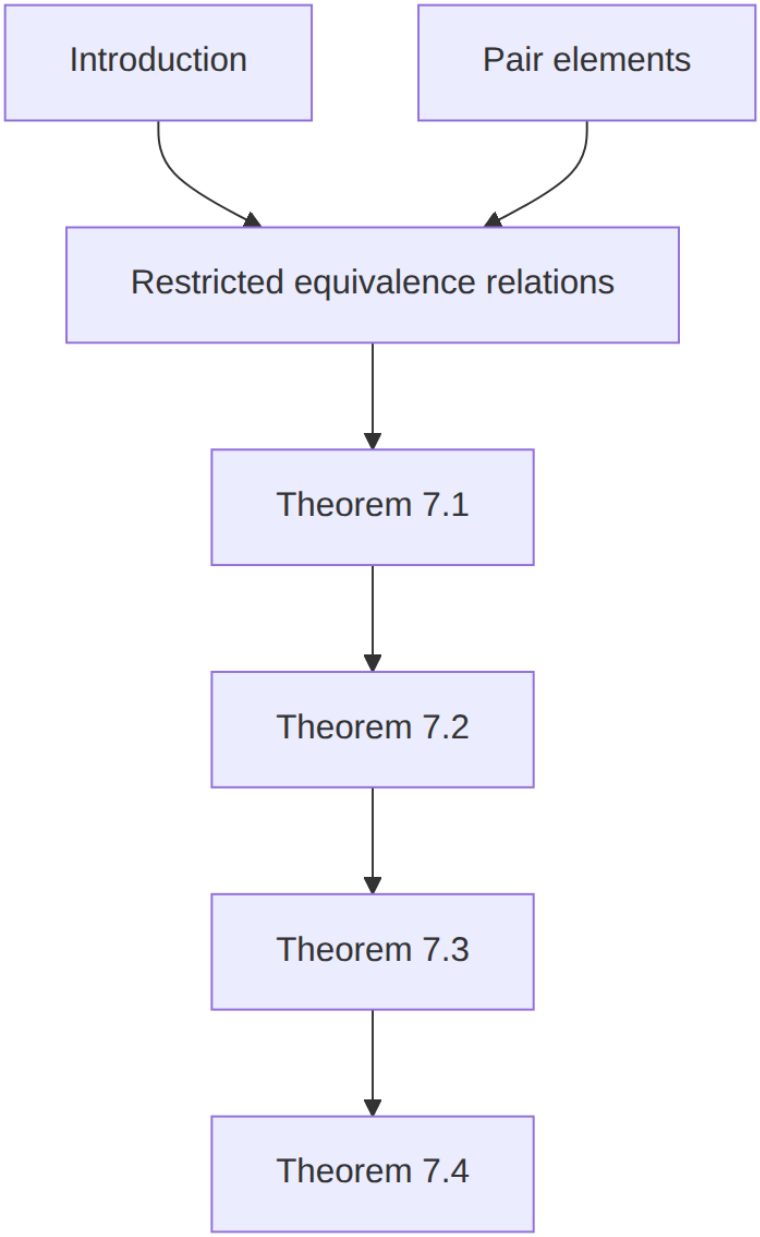

Figure 37: Total functions and functionality.

3.8.1 Introduction ✓

There is an inevitable conflict between the concepts of *total* and *partial* functions: we desire the former, but it is the latter we usually get. Total functions are better because they are "well-defined" at all their arguments, but the rub is that there is no general way of deciding when a *definition* is going to be well-defined in all its

uses. In analysis we have singularities, and in recursion theory we have endless, nonfinishing computations. In the present theory we have in effect evaded the question in two ways. First we have embraced the partial function as the norm. But secondly, and possibly confusingly, the multiple-valued functions are normal, total functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$. The point, of course, is that we are making a *model* of the partial functions in terms of ordinary mathematical functions. But note that the success of the *model* lies in *not* using arbitrary functions: it is only the continuous functions that correspond to the kind of partial functions we wanted to study. It would be a mistake to think of the variables in λ-calculus as ranging over arbitrary functions—and this mistake was made by both Church and Curry. The fixed-point operator $\mathbf{Y}$ shows that we must restrict attention to functions which do have fixed points. It is certainly the case that $\mathbf{P}\omega$ is not the only model for the λ-calculus, but it is a very satisfactory model and is rich enough to illustrate what can and what cannot be done with partial functions.

Historical note. Functionality had long been studied in combinatory logic. [32] is the introduction Scott used. This section is his reading of that theory in $\mathbf{P}\omega$. The connection with the functional interpretation of intuitionistic logic goes back to Curry and Kleene, and Theorem 7.3 is the standard result of that interpretation. Theorem 7.4, that the obvious typing characterizes the iterators, is due to Gordon Plotkin.

Whatever the pleasures of partial functions (and the multiple-valued ones, too), the desire for total functions remains. Take the integers. We are more interested in ω than $\omega \cup \{\bot, \top\}$. Since the multiple values $\bot$ and $\top$ are but two in number, it is easy to avoid them. The problem becomes tiresome in considering functions, however. The lattice represented by the retract $\mathbf{int} \circ \to \mathbf{int}$ is much too large, in that there are as many nontotal functions in this domain as total ones. The aim of the present section is to introduce an interpretation of a theory of functionality in the model $\mathbf{P}\omega$ that provides a convenient way of restricting attention to the functions (or other objects) that are total in the desired sense. The theory of functionality is rather like proposals of Curry, but not quite the same for important reasons as we will see.

In the theory of retracts of §§ 5 and 6, the plan of "restricting attention" was the very simple one of restricting to a *subset*. It was made notationally simple as the subsets in question could be parameterized by continuous functions. The retraction mappings stand in for their ranges. Even better, certain continuous functions act on these retractions as space-forming functors (such as $\oplus$ and $\circ \to$), which gives greater notational simplicity because one language is able to serve for several

tasks. When we pass to the theory of total functions, this same kind of simplicity is no longer possible owing to an increase in quantifier complexity in the necessary definitions. (This remark is made definite below.) Another point where there is some loss of simplicity concerns the representation of entities in $\mathbf{P}\omega$: subsets will no longer be enough, since we will need *quotients* of subsets. This is not a very startling point. Many constructions are affected in a natural way via equivalence classes. An equivalence relation makes you blind to certain distinctions. It may be easier also to remain a bit blind than to search for the most beautiful representative of an equivalence class: there may be nothing to choose between several candidates, and it can cost too much effort to attempt a choice. Thus our first agreement is that for many purposes a *kind* of object can be taken as a set of equivalence classes for an equivalence relation on a subset of $\mathbf{P}\omega$.

Because $\mathbf{P}\omega$ is closed under the pairing function $\lambda x \lambda y.\, \langle x, y\rangle$, we shall construe relations on subsets of $\mathbf{P}\omega$ as subsets of $\mathbf{P}\omega$ all of whose elements are ordered pairs. That is, a relation A satisfies this inclusion:

$$(7.1) \quad A \subseteq \{\langle x, y\rangle \mid x, y \in \mathbf{P}\omega\}.$$

3.8.2 Pair elements ✓

Ordered pairs of elements of $\mathbf{P}\omega$, as length-2 sequences.

Definition (`pairElem`). $\langle x, y\rangle = \mathrm{seq}_2(x, y)$.

Theorem (`pairElem.tag_ne`). $\langle 0, x\rangle \neq \langle 1, y\rangle$.

Proof. Distinct tags on length-2 sequences. ■

Theorem (`pairElem.eq_pairSeq`). $\langle x, y\rangle$ agrees with the retract pairing $\mathrm{pairSeq}(x, y)$.

Proof. Both are $\mathrm{seq}_2(x, y)$. ■

Theorem (`pairElem.fst`). $\langle x, y\rangle_0 = x$.

Proof. The zero coordinate of a length-2 sequence. ■

Theorem (`pairElem.snd`). $\langle x, y\rangle_1 = y$.

Proof. The one coordinate of a length-2 sequence. ■

Theorem (`pairElem.inj`). If $\langle x, y\rangle = \langle x', y'\rangle$, then $x = x'$ and $y = y'$.

Proof. Project both sides with the first and second coordinates. ■

3.8.3 Restricted equivalence relations ✓

DEFINITION. A (restricted) *equivalence relation* on $\mathbf{P}\omega$ is a symmetric and transitive relation on $\mathbf{P}\omega$.

Such relations are restricted because they are only reflexive on their domains—which are the same as their ranges—and these are the subsets with which the relations are concerned. We shall write $x\,A\,y$ for $\langle x, y\rangle \in A$ and $x : A$ for $x\,A\,x$. What we assume about these relations is the following:

$$(7.2) \quad x\,A\,y \text{ implies } y\,A\,x.$$

$$(7.3) \quad x\,A\,y \text{ and } y\,A\,z \text{ imply } x\,A\,z.$$

In case a is a retract, we introduce an equivalence relation to correspond:

$$(7.4) \quad E_a = \{\langle x, x\rangle \mid x : a\}.$$

This is the identity relation restricted to the range of a. Such relations (for obvious reasons) and many others satisfy an additional *intersection property*:

$$(7.5) \quad x\,A\,y \text{ and } x\,A\,z \text{ imply } x\,A\,(y \cap z).$$

We shall not generally assume (7.5) in this short discussion, but it is often convenient.

Each equivalence relation represents a *space*: the space of all its equivalence classes. Such spaces form a category more extensive than the category of retracts studied above. The familiar functors can be extended to this larger category by these definitions:

$$(7.6) \quad A \to B = \{\langle \lambda x.\, u(x), \lambda x.\, v(x)\rangle \mid u(x)\,B\,v(y) \text{ whenever } x\,A\,y\},$$

$$(7.7) \quad A \times B = \{\langle \langle x, x'\rangle, \langle y, y'\rangle\rangle \mid x\,A\,y \text{ and } x'\,B\,y'\},$$

$$(7.8) \quad A + B = \{\langle \langle 0, x\rangle, \langle 0, y\rangle\rangle \mid x\,A\,y\} \cup \{\langle \langle 1, x'\rangle, \langle 1, y'\rangle\rangle \mid x'\,B\,y'\}.$$

Formalization. Restricted equivalences are packaged as a structure with a binary relation that is symmetric and transitive. Membership $x : A$ is reflexivity $x\,A\,x$. The retract identity E_a, the functors (7.6)–(7.8), and the empty and singleton equivalences are the constructions below; symmetry and transitivity of each are part of the definition.

Definition (`RestrictedEquiv`). A restricted equivalence is a relation A on $\mathbf{P}\omega$ satisfying (7.2) and (7.3).

Definition (`RestrictedEquiv.mem`). $x : A$ means $x\,A\,x$.

Definition (`RestrictedEquiv.Ea`). E_a relates x to y just when $x : a$, $y : a$, and $x = y$.

Definition (`RestrictedEquiv.arrowE`). $A \to B$ relates f to g when both are graphs of their own application and $x\,A\,y$ implies $f(x)\,B\,g(y)$.

Definition (`RestrictedEquiv.prodE`). $A \times B$ relates u to v when both are pairs of their projections and the projections are related in A and in B respectively.

Definition (`RestrictedEquiv.sumE`). $A + B$ relates u to v when both are left injections whose payloads are related in A, or both are right injections whose payloads are related in B.

Definition (`RestrictedEquiv.emptyE`). The empty restricted equivalence relates nothing.

Definition (`RestrictedEquiv.singletonE`). The singleton on a relates x to y just when $x = y = a$.

Theorem (`singletonE.mem`). x is a member of the singleton on a if and only if $x = a$.

Proof. Unfold membership as $x\,A\,x$. ■

Definition (`RestrictedEquiv.Nk`). N_k relates x to y when $x = y = \overline{n}$ for some $n < k$.

Definition (`RestrictedEquiv.Nrel`). N relates x to y when $x = y = \overline{n}$ for some $n \in \omega$.

Definition (`RestrictedEquiv.kerE`). The kernel of a relates x to y when $a(x) = a(y)$.

Theorem (`kerE.repr`). If a is a retract, then x is kernel-related to $a(x)$.

Proof. Retract-fixedness gives $a(a(x)) = a(x)$. ■

Definition (`iterateE`). The iterate equivalence at f and x relates u to v when $u = v = Z(n, f, x)$ for some n.

3.8.4 Theorem 7.1 ✓

THEOREM 7.1 (The closure theorem). *If A and B are restricted equivalence relations, then so are $A \to B$, $A \times B$ and $A + B$. We find:*

(i) $f : A \to B$ iff $f = \lambda x.\, f(x)$ and whenever $x\, A\, y$, then $f(x)\, B\, f(y)$, in particular:

(ii) if $f : A \to B$ and $x : A$, then $f(x) : B$; furthermore,

(iii) $u : A \times B$ iff $u = \langle u_0, u_1 \rangle$ and $u_0 : A$ and $u_1 : B$;

(iv) $u : A + B$ iff either $u = \langle 0, u_1 \rangle$ and $u_1 : A$ or $u = \langle 1, u_1 \rangle$ and $u_1 : B$.

It follows easily from (7.1) that the restricted equivalence relations form a Cartesian closed category which—in distinction to the category of retracts—has disjoint sums (or coproducts as they are usually called in category theory). This result is probably a special case of a more general theorem. The point is that $\mathbf{P}\omega$ itself is a space in a Cartesian closed category (that of continuous lattices and continuous maps) and it contains as subspaces the Boolean space and especially its own function space and Cartesian square. In this circumstance any such rich space must be such that its restricted equivalence relations again form a good category. Our construction is not strictly categorical in nature, as we have used the elements of $\mathbf{P}\omega$ and have relied on being able to form arbitrary subsets (arbitrary relations). But a more abstract formulation must be possible. The connection with the category of retracts is indicated in the next theorem.

Formalization. The closure theorem unpacks membership in $A \to B$, $A \times B$, and $A + B$ against the definitions of those functors. Symmetry and transitivity of the functors themselves are already part of those constructions.

Theorem (`theorem_7_1`). For restricted equivalences A and B: (i) $f : A \to B$ if and only if f equals the graph of its own application and $x\, A\, y$ implies $f(x)\, B\, f(y)$; (ii) if $f : A \to B$ and $x : A$, then $f(x) : B$; (iii) $u : A \times B$ if and only if $u = \langle u_0, u_1 \rangle$ with $u_0 : A$ and $u_1 : B$; (iv) $u : A + B$ if and only if $u = \langle 0, u_1 \rangle$ with $u_1 : A$, or $u = \langle 1, u_1 \rangle$ with $u_1 : B$.

Proof. Each clause is an unpacking of membership in the corresponding functor: for the arrow, the two graph conjuncts collapse under $f = g$; preservation on a related pair yields (ii) at $x\, A\, x$; for the product and sum, the paired projections (resp. common injection tag) reduce relatedness of two copies of u to membership of the components. ■

3.8.5 Theorem 7.2 ✓

THEOREM 7.2 (The isomorphism theorem). *If a and b are retracts, we have the following isomorphisms and identities relating the spaces:*

(i) $E_a \cong \{\langle x, y\rangle \mid a(x) = a(y)\}$;

(ii) $E_{a\circ\to b} \cong E_a \to E_b$;

(iii) $E_{a\otimes b} = E_a \times E_b$;

(iv) $E_{a\oplus b} = E_a + E_b \cup \{\langle\bot,\bot\rangle, \langle\top,\top\rangle\}$.

Part (iv) is not categorical in nature as it stands, but (ii) and (iii) indicate that E is a functor from the category of retracts into the category of equivalence relations that shows that the former is a full sub-Cartesian-closed category of the latter. We cannot pursue the categorical questions here, but note that there are many subcategories that might be of interest; for example, the equivalence relations with the intersection property are closed under $\to$, $\times$, and $+$.

Returning to the question of total functions we introduce this notation:

$$(7.9) \quad N = \{\langle n, n\rangle \mid n \in \omega\}.$$

This is the type of the integers *without* $\bot$ and $\top$, i.e., the total integers. We note that:

$$(7.10) \quad N = \{u \mid u = \langle u_0, u_0\rangle,\ u_0 = \mathbf{int}(u_0),\ \mathbf{mid}(u_0) = 0\}.$$

Thus N is a $\mathfrak{B}_\delta$-set. What is $N \to N$? We see:

$$\{(7.11) \quad f : N \to N \text{ iff } f : \mathbf{fun} \text{ and } f(n) \in \omega \text{ whenever } n \in \omega.\}$$

This $N \to N$ is indeed the type of all total functions from ω into ω. It can be shown that $N \to N$ is also a $\mathfrak{B}_\delta$-set: good. But what is $(N \to N) \to N$? This is no longer a $\mathfrak{B}_\delta$-set, the best we can say is Π^1_1. By Theorem 7.1 it corresponds to the type of all

(extensional) *continuous* total functions from $N \to N$ into N. (The condition on A and B on the right side of (7.6) makes the concept of function embodied in $A \to B$ extensional, since the functions are meant to preserve the equivalence relations.)

A more precise discussion identifies $N \to N$ as a topological space, usually called the *Baire space*. If we introduce the finite discrete spaces by:

$$(7.12) \quad N_k = \{\langle n, n\rangle \mid n < k\},$$

then $N \to N_2$ can also be identified with a topological space, usually called the *Cantor space*. In this identification we find at the next type, say either $(N \to N) \to N$ or $(N \to N_2) \to N_2$, that elements correspond to the usual notion of continuous function defined in topological terms. However, these higher type spaces are not at all conveniently taken as *topological* spaces. Certain of them can be identified as *limit spaces* according to the work of Hyland, and for these $\to$, $\times$, and $+$ have the natural interpretation. We cannot enter into these details here, but we can remark that the higher type spaces become ever more complicated. Thus $((N \to N) \to N) \to N$ is a Π^1_2-set and each $\to$ will add another quantifier to the definition. This is reasonable, because to say that a function is total is to say that *all* its values are well-behaved. But if its domain is a complex space, this statement of totality is even more complex. Despite this complexity, however, it is possible to sort out what kind of mapping properties many functions have. We shall mention a few of the combinators.

Formalization. The isomorphism theorem relates the retract identity E_a to kernels, arrows, products, and sums. The packaging theorem assembles the four clauses for retracts a and b.

Theorem (`theorem_7_2.i`). $x\ E_a\ y$ if and only if $x : a$, $y : a$, and $x = y$.

Proof. Unfolding the definition of E_a. ■

Theorem (`theorem_7_2.i_iso`). If a is a retract, then $a(x) = a(y)$ if and only if $a(x)\ E_a\ a(y)$.

Proof. Both sides reduce to equality of the images once retract-fixedness supplies $a(x) : a$ and $a(y) : a$. ■

Theorem (`theorem_7_2.ii_of_typed`). If $f : a\circ \to b$, then $f : E_a \to E_b$.

Proof. Typing into the retract arrow rewrites f as a graph; relatedness in E_a is equality of a-typed points, and the retract arrow preserves typing into b. ■

Theorem (`theorem_7_2.ii`). For retracts a and b, typing into $a\circ \to b$ implies membership in $E_a \to E_b$; relatedness in $E_a \to E_b$ passes to relatedness of the retract-arrow applications in $E_{a\circ\to b}$ and conversely.

Proof. The forward typing clause is the previous theorem; the two directions between $E_a \to E_b$ and $E_{a\circ\to b}$ compare graph preservation on a-fixed arguments with equality after applying $a\circ \to b$. ■

Theorem (`theorem_7_2.iii`). On paired arguments, $E_{a\otimes b}$ agrees with $E_a \times E_b$.

Proof. Unpack tensor typing of a pair into component typings, or reassemble them. ■

Theorem (`theorem_7_2.iii_exact`). For arbitrary u and v, $u\, E_{a\otimes b}\, v$ if and only if $u\, (E_a \times E_b)\, v$.

Proof. Reduce via the product membership characterisation of Theorem 4.4 to the previous clause on pairs. ■

Theorem (`theorem_7_2.iv`). For retracts a and b, $u\, E_{a\oplus b}\, v$ if and only if $u\, (E_a + E_b)\, v$, or both are $\bot$, or both are $\top$.

Proof. Case on the sum typing of u: bottom, top, left injection, or right injection; the converse rebuilds sum typing from the sum equivalence or the two exceptional pairs. ■

Theorem (`theorem_7_2`). For retracts a and b, clauses (i)–(iv) of the isomorphism theorem hold.

Proof. Assemble the four preceding tools. ■

3.8.6 Theorem 7.3 ✓

THEOREM 7.3 (The functionality theorem). *The combinators* **I**, **K**, *and* **S** *enjoy the following functionality properties which hold for all equivalence relations A, B, C:*

(i) $\mathbf{I} : A \to A$;

(ii) $\mathbf{K} : A \to (B \to A)$;

(iii) $\mathbf{S} : (A \to (B \to C)) \to ((A \to B) \to (A \to C))$.

Furthermore, these combinators are uniquely determined by these properties.

Let us check that S satisfies (iii). Suppose that:

$$f\,(A \to (B \to C))\,f'.$$

We must show that:

$$\mathbf{S}(f)\,((A \to B) \to (A \to C))\,\mathbf{S}(f').$$

To this end suppose that:

$$g\,(A \to B)\,g'.$$

We must show that:

$$\mathbf{S}(f)(g)\,(A \to C)\,\mathbf{S}(f')(g').$$

To this end suppose that:

$$x\,A\,x'.$$

We must show that:

$$\mathbf{S}(f)(g)(x)\,C\,\mathbf{S}(f')(g')(x').$$

Now by definition of the combinator $\mathbf{S}$ we have:

$$\mathbf{S}(f)(g)(x) = f(x)(g(x)),$$

$$\mathbf{S}(f')(g')(x') = f'(x')(g'(x')).$$

By assumptions on g, g' and on x, x', we know:

$$g(x)\,B\,g'(x').$$

By assumptions on f, f' and on x, x', we know:

$$f(x)\,(B \to C)\,f'(x').$$

The desired conclusion now follows when we note such combinations as $\mathbf{S}(f)$ and $\mathbf{S}(f)(g)$ are indeed functions. (We are using Theorem 7.1(i) several times in this case.)

In the case of the converse, let us suppose by way of example that $k \in \mathbf{P}\omega$ is such that

$$k : A \to (B \to A)$$

holds for all equivalence relations A and B. By specializing to, say, the identity relation we see that whatever $a \in \mathbf{P}\omega$ we take, both k and $k(a)$ are functions. To establish that $k = \mathbf{K}$ we need to show that the equation:

$$k(a)(b) = a$$

holds for all $a, b \in \mathbf{P}\omega$. This is easy to prove, for we have only to set:

$$A = \{\langle a, a\rangle\} \quad \text{and} \quad B = \{\langle b, b\rangle\},$$

and the equation follows at once. Not all proofs are quite so easy, however.

In the case of the combinator $\mathbf{S}$ it is not strictly true to say that Theorem 7.3(iii) determines it outright. The exact formulation is this: if $s \in \mathbf{P}\omega$ is such that

$$s(f) = s(\lambda x \lambda y.\, f(x)(y)) \quad \text{and} \quad s(f)(g) = s(f)(\lambda x.\, g(x))$$

for all $f, g \in \mathbf{P}\omega$; and if

$$s : (A \to (B \to C)) \to ((A \to B) \to (A \to C))$$

for all A, B, C, then $s = \mathbf{S}$. In other words, we need to know that s converts its first two arguments into functions with the right number of places before we can say that its explicit functionality identifies it as being the combinator $\mathbf{S}$.

In [32] they show that the functionality property:

$$(7.13) \quad \lambda f \lambda g.\, f \circ g : (B \to C) \to ((A \to B) \to (A \to C)),$$

follows from Theorem 7.1(ii) and Theorem 7.3(ii) and (iii) in view of the identity:

$$(7.14) \quad \lambda f \lambda g.\, f \circ g = \mathbf{S}(\mathbf{K}(\mathbf{S}))(\mathbf{K})$$

(see the proof of Theorem 2.4).

A more interesting result concerns the *iterators* defined as follows:

$$(7.15) \quad \mathbf{Z}_0 = \lambda f \lambda x.\, x,$$

$$(7.16) \quad \mathbf{Z}_{n+1} = \lambda f \lambda x.\, f(\mathbf{Z}_n(f)(x)),$$

In other words, $\mathbf{Z}_n(f)(x) = f^n(x)$. These natural combinators can be typed very easily, but Gordon Plotkin has shown that the obvious typing actually characterizes them.

Formalization. Functionality of $\mathbf{I}$, $\mathbf{K}$, and $\mathbf{S}$ for all restricted equivalences, together with uniqueness under those typings (with the η-hypotheses for $\mathbf{S}$).

Theorem (`theorem_7_3.i`). $\mathbf{I} : A \to A$ for every restricted equivalence A.

Proof. $\mathbf{I}$ is a graph and preserves relatedness by acting as the identity. ■

Theorem (`theorem_7_3.ii`). $\mathbf{K} : A \to (B \to A)$ for all restricted equivalences A and B.

Proof. $\mathbf{K}$ and its applications are graphs; relatedness of the first arguments is preserved by discarding the second. ■

Theorem (`theorem_7_3.iii`). $\mathbf{S} : (A \to (B \to C)) \to ((A \to B) \to (A \to C))$ for all restricted equivalences A, B, and C.

Proof. Nested graphhood of $\mathbf{S}$ and its curried applications; at related x, x' the applications $g(x)$ and $f(x)$ are related in B and $B \to C$, so $f(x)(g(x))$ is related in C. ■

Theorem (`theorem_7_3.I_unique`). If $i : A \to A$ for every restricted equivalence A, then $i = \mathbf{I}$.

Proof. Specialize to singletons: $i(a)$ is related to itself in the singleton on a, so $i(a) = a$. ■

Theorem (`theorem_7_3.K_unique`). If $k : A \to (B \to A)$ for all restricted equivalences A and B, then $k = \mathbf{K}$.

Proof. Specialize to singletons on a and b: $k(a)(b)$ lies in the singleton on a, so equals a. ■

Theorem (`theorem_7_3.S_unique`). If s is η-stable in its first two arguments as in Scott's proviso, and $s : (A \to (B \to C)) \to ((A \to B) \to (A \to C))$ for all A, B, C, then $s = \mathbf{S}$.

Proof. Reduce to η-normalized arguments, then evaluate at a singleton argument: the typing forces $s(f)(g)(x) = f(x)(g(x))$. ■

Theorem (`theorem_7_3`). The functionality and uniqueness clauses of Theorem 7.3 hold.

Proof. Assemble the six preceding tools. ■

3.8.7 Theorem 7.4 ✓

THEOREM 7.4 (The iterator theorem). *The combinators $\mathbf{Z}_n$ enjoy the following functionality property which holds for all equivalence relations A:*

(i) $\mathbf{Z}_n : (A \to A) \to (A \to A)$.

Further, if any element $z \in \mathbf{P}\omega$ satisfies (i) for all A, then it must be one of the iterators, provided that $z(f) = z(\lambda x.\, f(x))$ holds for all $f \in \mathbf{P}\omega$.

That each of the $\mathbf{Z}_n$ satisfies Theorem 7.4(i) is obvious. Suppose z were another such element. Then clearly:

$$z = \lambda f \lambda x.\, z(f)(x).$$

Suppose f and x are fixed for the moment. Let:

$$A = \{(f^n(x), f^n(x)) \mid n \in \omega\},$$

where we can suppose in addition that:

$$f = \lambda x.\, f(x).$$

Then $f : A \to A$ is clear, and so $z(f) : A \to A$ also. But $x : A$, therefore $z(f)(x) = f^n(x)$, for some $n \in \omega$, because $z(f)(x) : A$. The trouble with this easy part of the argument is that the integer n depends on f and x. What we must show is that it is independent of f and x; then $z = \mathbf{Z}_n$ will follow.

Plotkin's method for this case is to introduce some independent successor functions:

$$\sigma_j = \lambda x.\, \{(j, k+1) \mid (j, k) \in x\}. \tag{7.17}$$

Note that:

$$\sigma_j^m((j', 0)) = \begin{cases} (j, m) & \text{if } j = j'; \\ \bot & \text{if } j \neq j'. \end{cases} \tag{7.18}$$

It then follows that:

$$(\sigma_j \cup \sigma_{j'})^m((j, 0) \cup (j', 0)) = (j, m) \cup (j', m). \tag{7.19}$$

Having these identities, we return to the argument. From what we saw before, given $j \in \omega$, there is an n_j such that:

$$z(\sigma_j)((j, 0)) = \sigma_j^{n_j}((j, 0)) = (j, n_j)$$

Take any two $j, j' \in \omega$. We also know there is an $n \in \omega$ where:

$$z(\sigma_j \cup \sigma_{j'})((j, 0) \cup (j', 0)) = (j, n) \cup (j', n).$$

in view of (7.19). But since $\sigma_j \subseteq \sigma_j \cup \sigma_{j'}$ and $\sigma_{j'} \subseteq \sigma_j \cup \sigma_{j'}$, we have:

$$(j, n_j) \cup (j', n_{j'}) \subseteq (j, n) \cup (j', n).$$

It follows that

$$n_j = n = n_{j'},$$

and so they are all equal. This determines the fixed $n \in \omega$ we want.

Suppose that both f and x are finite sets in $\mathbf{P}\omega$. Choose $j > \max(f \cup x)$. Let A this time be the least equivalence relation such that:

$$f^m(x)\, A\, f^m(x) \cup (j, m)$$

holds for all $m \in \omega$. We then check that:

$$\lambda x.\, f(x)\, (A \to A)\, (\lambda x.\, f(x)) \cup \sigma_j.$$

Therefore, we have:

$$z(\lambda x.\, f(x))\, (A \to A)\, z((\lambda x.\, f(x)) \cup \sigma_j),$$

and since $x\, A\, x \cup (j, 0)$, we get:

$$z(\lambda x.\, f(x))(x)\, A\, z((\lambda x.\, f(x)) \cup \sigma_j)(x \cup (j, 0)).$$

Now there is an integer $m \in \omega$ such that:

$$\begin{aligned} z((\lambda x.\, f(x)) \cup \sigma_j)(x \cup (j, 0)) &= f^m(x) \cup \sigma_j^m((j, 0)) \\ &= f^m(x) \cup (j, m), \end{aligned}$$

where we have been able to separate f and σ because j is so large. But the right-hand side must contain $z(\sigma_j)(j, 0) = (j, n)$. Thus m and our fixed n are the same. The other element

$$z(\lambda x.\, f(x))(x) = f^q(x)$$

for some $q \in \omega$. Thus we have:

$$f^q(x)\, A\, f^n(x) \cup (j, n).$$

Again since j is so large, $(j, n) \notin f^q(x)$. Thus by our choice of A we must have $f^q(x) = f^n(x)$. This means then, since n is fixed, that for *all finite* f, x:

$$z(\lambda x.\, f(x))(x) = f^n(x).$$

But then by continuity this equation holds for *all* f, x. It follows now that $z = \mathbf{Z}_n$, by the proviso of the theorem.

These results bring up many questions which we leave unanswered here. For example, which combinators (i.e., pure λ-terms) have functionality as in the examples above, and can we decide when a term is one such? In particular, can the diagonal combinator $\lambda x.\, x(x)$ be typed? (The argument of [32, p. 81] is purely formal and does not apparently apply to the model.) What about terms in LAMBDA beyond the pure λ-calculus?

Formalization. The iterator theorem packages Plotkin's tag-erasure argument: successor identities for σ_j, a restricted equivalence that pairs finite orbits with fresh tags, and uniqueness of any η-normalized z that is functional at every $(A \to A) \to (A \to A)$.

Definition (`eraseTag`). Erase tag j from u by discarding every pair whose first component is j.

Theorem (`eraseTag.Z_finite`). On a finite orbit $Z_m(e_p, e_q)$, erasing the fresh tag $\max(p, q) + 1$ leaves the orbit unchanged.

Proof. Finite orbits never carry that fresh tag. ■

Theorem (`eraseTag.Z_finite_union`). Erasing the fresh tag from an orbit union a fresh singleton recovers the plain orbit.

Proof. Membership either lies in the orbit (kept) or is the fresh pair (discarded). ■

Definition (`plotkinGood`). An element is Plotkin-good when it is a finite orbit of e_p on e_q, or that orbit union the fresh singleton at step m.

Definition (`plotkinRel`). The generating relation identifies an orbit with the same orbit union its fresh singleton at the same step, in either order.

Definition (`plotkinE`). The Plotkin equivalence relates good elements whose equivalence closure under that generating relation identifies them.

Theorem (`plotkinE.erase`). Related elements have equal erase-tag projections at the fresh tag.

Proof. Induction on the generated equivalence, using the two erase-tag orbit identities. ■

Theorem (`plotkinE.finite_separation`). Iterating the η-normalized finite graph of e_p united with σ_j on e_q union a fresh zero yields the finite orbit union the fresh singleton.

Proof. Induction on the iterate, separating e_p from σ_j by freshness of the tag. ■

Theorem (`plotkinE.function_related`). The η-normalized graph of e_p is related in $A \to A$ to that graph united with σ_j, for A the Plotkin equivalence at the fresh tag.

Proof. Both sides are graphs; on related arguments, erase-tag agreement and the four orbit/singleton cases produce related results. ■

Theorem (`eq_7_18_eq`). $\sigma_j^m(\{(j, 0)\}) = \{(j, m)\}$.

Proof. Induction, applying the successor-on-singleton law for σ_j. ■

Theorem (`eq_7_18_ne`). If $j \neq j'$, then $\sigma_j^{m+1}(\{(j', 0)\}) = \bot$.

Proof. Induction: the first step kills a wrong tag, and σ_j preserves $\bot$. ■

Theorem (`eq_7_19`). $(\sigma_j \cup \sigma_{j'})^m(\{(j, 0)\} \cup \{(j', 0)\}) = \{(j, m)\} \cup \{(j', m)\}$.

Proof. Equal tags reduce to the previous identity; distinct tags induct using the pairwise successor law. ■

Theorem (`theorem_7_4.i`). Each iterator $\mathbf{Z}_n$ is a member of $(A \to A) \to (A \to A)$ for every restricted equivalence A.

Proof. Iterators are graphs, and relatedness is preserved by the iterate law for Z. ■

Theorem (`theorem_7_4.plotkin`). If z is η-normalized and functional at every $(A \to A) \to (A \to A)$, then for any f and x there is an n with $z(f)(x) = f^n(x)$.

Proof. Specialize to the iterate equivalence of the η-normalized f at x; functionality forces the value into that orbit. ■

Theorem (`theorem_7_4.finite`). Under those hypotheses, if $z(\sigma_j)(\{(j, 0)\}) = \{(j, n)\}$ for every j, then on finite e_p and e_q one has $z(e_p)(e_q) = e_p^n(e_q)$.

Proof. Relate the η-normalized finite graph to its union with a fresh σ_j in the Plotkin equivalence; compare orbits by erase-tag, and force the iterate index to equal the fixed n by a fresh-tag witness. ■

Theorem (`theorem_7_4.sigma_index`). Under those hypotheses there is a single n such that $z(\sigma_j)(\{(j, 0)\}) = \{(j, n)\}$ for every j.

Proof. Compare the indices at 0, at j, and at their union via (7.18)–(7.19) and monotonicity of application. ■

Theorem (`theorem_7_4.unique`). Under those hypotheses, $z = \mathbf{Z}_n$ for that n.

Proof. On finite arguments the previous two tools give agreement with $\mathbf{Z}_n$; continuity and η-normalization extend to all arguments, then graph extensionality. ■

Theorem (`theorem_7_4`). Every $\mathbf{Z}_n$ is functional at all $(A \to A) \to (A \to A)$, and every η-normalized z with that functionality is some $\mathbf{Z}_n$.

Proof. Assemble the membership and uniqueness tools. ■

3.9 Acknowledgements and references

Appendix B. Acknowledgments and references. My greatest overall debt is to the late Christopher Strachey, who provided not only the initial stimulus and continuing encouragement, but also what may be termed the necessary irritation. Not being a trained mathematician, he often assumed that various operations made sense without looking too closely or rigorously at the details. This was particularly the case with the λ-calculus, which he used as freely as everyday algebra. Having repeatedly and outspokenly condemned the λ-calculus as a formal system without clear mathematical foundations, it was up to me to provide some alternative. The first suggestion was a typed system put forward in [33] (unpublished, but later developed as LCF by Robin Milner and his collaborators). Experience with the type structure of function spaces, which had come to my attention from work in recursion theory by Nerode, Platek and others, soon convinced me that there were many more similar structures than might at first be imagined. In particular, a vague idea about a space with a "dense" basis led quickly to the more direct construction, by inverse limits, of function spaces of "infinite" type that were very reasonable models of the classical "type-free" λ-calculus (as well as many other calculi for other "reflexive domains"). The details can be found in [29] and [34]. Algebra was justified, but the work in doing so was tiring and the exact connections with computability were not all that easy to describe.

In the meantime [35] contained suggestions for a "set-theoretical" construction of models, but not much notice was taken of the plan at the time it was circulated—perhaps owing to a fairly sketchy presentation of the precise semantics of the λ-calculus. The present paper evolved particularly from the project of making the connections with ordinary recursion theory easier to comprehend, since a satisfactory theory of computability and programming language semantics had to face this problem. The idea of using sets of integers for a model was first put forward by the author at a meeting at Oberwolfach at Easter in 1973 and in a more definitive form at the Third Scandinavian Logic Symposium shortly thereafter (see [36] which is a preliminary and shorter version of this paper). The author gave a report on the model at the Bristol Logic Colloquium in July 1973, but did not submit a paper for the proceedings. A series of several lectures was presented at the Kiel Logic Colloquium in July 1974, covering most of the present paper which was dis-

tributed as a preprint at the meeting. The text (but unfortunately neither acknowledgments nor references) was printed in the proceedings (Springer Lecture Notes in Mathematics, vol. 499). In 1973 after experimentation with definitions somehow forced him into the definition of the model, the author realized that it was essentially the same as Plotkin's idea and, even more surprising, it was already implicit in a very precise form in much earlier work by [20] and [37] (see also [21]) on *enumeration operators*. What had happened was that Plotkin had not made enough tie-up with recursion theory, and the recursive people had not seen the tie-up with λ-calculus, even though they knew that one could do a lot with such operators. Actually, if the author had taken his own advice in 1971 (see *Continuous lattices*, [19, end of § 2]), he would have seen that many spaces have their own continuous-function spaces as computable retracts, a fact which is just exactly the basis for the present construction; but instead he said: "it [the representation as a retract] does not seem to be of too much help in proving theorems."

Over the years in work on λ-calculus and programming language semantics, personal contact and correspondence with a large number of people has been very stimulating and helpful. I must mention particularly de Bakker, Barendregt, Bekic, Blikle, Böhm, Curry, Egli, Engeler, Ershov, Goodman, Hyland, Kreisel, Landin, Milne, Milner, Mosses, Nivat, Park, Plotkin, Reynolds, de Roever, Smyth, Stoy, Tang, Tennent, Wadsworth. (I apologize to those I have inadvertently left out of this list.) In the reference list a very imperfect attempt has been made to collect references directly relevant to the topics of this paper as well as pointers to related areas that may be of inspiration for future work. The list of papers is undoubtedly incomplete, and inaccurate as well, but the author hopes it may be of some use for those seeking orientation. It is a very vexing problem to keep such references up to date. Some remarks toward references and acknowledgments on the specific results in the various sections follow. Felipe Bracho deserves special thanks for help in the preparation of the final manuscript and with the reference list.

Section 1. The relevance of the "positive" or "weak" topology first came to the author's attention through the work of [17]. Continuous functionals were studied by Kleene and Platek and many other researchers in recursion theory. Monotonicity was particularly stressed by [38]. The graphs and the definition of application are used in the same way by [35] and [21, see p. 147]. The fixed-point theorem is very well-known. See, e.g., [39]. The extension theorem was formulated by the author, but it is very similar to many results in point-set topology; it was used in a prominent way in [19] to characterize continuous lattices. The embedding theorem is well-known; see, e.g., [15].

Section 2. The language LAMBDA is due to the author. Note in particular that Plotkin and Rogers do not define λ-abstraction, even though they know of the existence of many combinators and *could have* defined abstraction if anyone had ever asked them. In particular, they understood about conversion in many instances. The reduction and combinator theorems are well known from combinatory logic and can be found in any reference. The first recursion theorem is basic to all of elementary recursion theory; what is new here is the adaptation of David Park's proof ([40], unpublished) to the present model to show that Curry's "paradoxical" combinator actually does the recursion. The definition of computability and the definability theorem tie up the present theory with the older theory of enumeration operators.

Section 3. The idea of reduction to a few combinators is an old one in combinatory logic; the author only needed to find a small trick (formula (3.1)) which would take care of the arithmetical combinators. The ideas for the Gödel numbering and the proof of the second recursion theorem are standard, as is the proof of the incompleteness theorem. It only looks a little different since we combine arithmetic with the "type-free" combinators. The proof of the completeness theorem for definability (Theorem 3.5) is taken directly from [20]. The author is indebted to Hyland for pointing this out. The subalgebra theorem is an easy reformulation of talk about enumeration degrees: for more information on such degrees consult [21], [22], and also [23]. The area is underdeveloped as compared to Turing degrees. Semigroups of combinators

have been discussed by Church and Böhm.

Section 4. The notion of a *retract* is common in topology, but the idea of using them to define data types and of having a calculus of computable retracts is original with the author. Of course the connection between lattices and fixed points was known; more about lattices is to be found in [19]. The various operations on retracts and the idea of using fixed-point equations to define retracts recursively are due to the author. Applications to semantics were given in [25] for flow diagrams, and this has been followed up by many people, in particular [26] and [27].

Section 5. Algebraic lattices have been known for a long time (see [30]) and also closure operations (see, e.g., [31]). It was Per Martin-Löf and Peter Hancock who suggested that they might form a "universe"; in particular the construction of $\mathbf{V}$ is essentially due to them. The limit theorem is due to the author.

Section 6. More information on the classification by notions in descriptive set theory of various subsets can be found in the work of Tang who also makes

Section 6. More information on the classification by notions in descriptive set theory of various subsets can be found in the work of Tang who also makes connections with the work of Wadge. The various normal forms for the classes of sets (e.g., Table 3) are due to the author.

Section 7. Functionality has been studied for some time in combinatory logic (see, e.g., [32] for an introduction). The author had the idea to see what it all means in the models; there are, of course, connections going back to Curry and Kleene, with functional interpretations of intuitionistic logic (cf. Theorem 7.3, which is well-known). The proof of Theorem 7.4 is due to Plotkin.

Retracts (Theorem 4.1). After the main body of the paper was written, Y. L. Ershov solved the author's problem about the space of retracts. Ershov's proof is presented after the discussion of the proof of Theorem 4.1 in the Retracts section. Quite independently [24] found almost exactly the same proof. Before corresponding with Ershov, the author was totally unaware of the connections with and the importance of Ershov's extensive work in "numeration" theory (see citations in the reference list).

All defects are due to the author.

4.1 Introduction

These notes were written in conjunction with the lectures delivered by me for the Semantics of Programming Languages sequence during Michaelmas Term 1980 at Oxford. I started writing around the first week of

October and finished at the end of November. The purpose of the course was to provide the foundations needed for the method of denotational semantics; in particular, I wanted to make the connections with recursive function theory more definite and to show explicit, effectively given solutions to domain equations. Roughly, these chapters cover the first half of the book of J.E. Stoy. I plan soon to expand the notes into a book by adding additional chapters on other theoretical topics that time did not permit me to cover in one eight-week term.

When I started writing Lecture I in October, I did not know what the later lectures would contain: I could see no further ahead than part of Lecture III in the beginning. The lectures had to be typed in advance of the class meetings, however, so there was at the time of composition no opportunity for second thoughts of any major proportions: I had to write the text straight through. As a consequence there are many remarks I would like to transpose and many additional points of explanation I see are needed; further worked examples and easier exercises are also required. During the spring, after receiving many helpful comments, I was able to introduce a few changes in the text and make some necessary corrections. However, a complete retyping was impossible. Nevertheless, this preliminary version of the book seems to provide a quite detailed introduction and is sufficient to exhibit the scope of the approach and several applications.

The idea of using neighbourhood systems to give set-theoretical representations of domains had been in the back of

my mind for some time in connection with specific examples. But the thought that a systematic development along these lines might be easier to follow than the more abstract lattice-theoretic and topological approach used by myself and others in many publications only came to me during the IFIP Working Group 2.2 meeting in Copenhagen in mid-June 1980. I gave a brief public presentation at ICALP '80 in Holland in mid-July.

One large mistake I have made is to de-emphasize partial orderings too much, since at the right point the concepts and the language are in fact helpful. The basic plan is that, instead of axiomatizing the theory using partial orderings, the necessary facts come out as *theorems*. For a neighbourhood system $\mathcal{D}$, the set of elements $|\mathcal{D}|$, which consists of filters, is naturally partially ordered. And approximable mappings naturally *preserve* the ordering. And so on. The advantage I see from the point of view of exposition is that properties can be brought out one at a time instead of having to put them down all in advance of any experience with the ideas. My own feeling after writing these chapters is that the plan has worked out far better than I could have dared to hope. I was especially glad that I could generate so many *exercises*, and I hope eventually to provide many more. One interesting place at which partial orderings prove their usefulness is in visualizing domains. As it stands now the text does not contain enough in the way of pictures. This will have to be remedied in a future version. Undoubtedly to include enough explanation, several of the lectures will have to be sub-divided into separate chapters.

One major improvement is needed: to bring Exercise 2.22 into the main text. I did not know in advance how often I would need this result for giving (easy) set-theoretical characterizations of domains and structure on them. This will be an easy repair, but it will cause quite a bit of rewriting. Clearly

much more has to be said about the interplay between elements and neighbourhoods. In particular, the character of the elements of a domain, like the power set of a set, has not been sufficiently illustrated, and quite a bit of expansion on this topic is also needed.

Finally I have to explain that I had no time whatsoever to put in references and a bibliography. The ideas I have used have occurred to many, many people who have worked on domains, and I do not wish to claim originality. I *am* claiming some advantage to my style of representation, but I fully realize that a published version will have to have detailed historical references and notes at the ends of the lectures. Needless to say I should very much appreciate any advice or criticism from readers of this preliminary version.

I would like to give a warm word of thanks to the many people who have already commented on the preliminary text both at Oxford and in Boston, where I gave lectures. Very special thanks are due to Steve Comer and Steve Brookes, who spent many hours proof reading the typescripts. The biggest word of thanks, however, is reserved for Elsie Hinkes who, under very considerable pressure, did a wonderful job of typing.

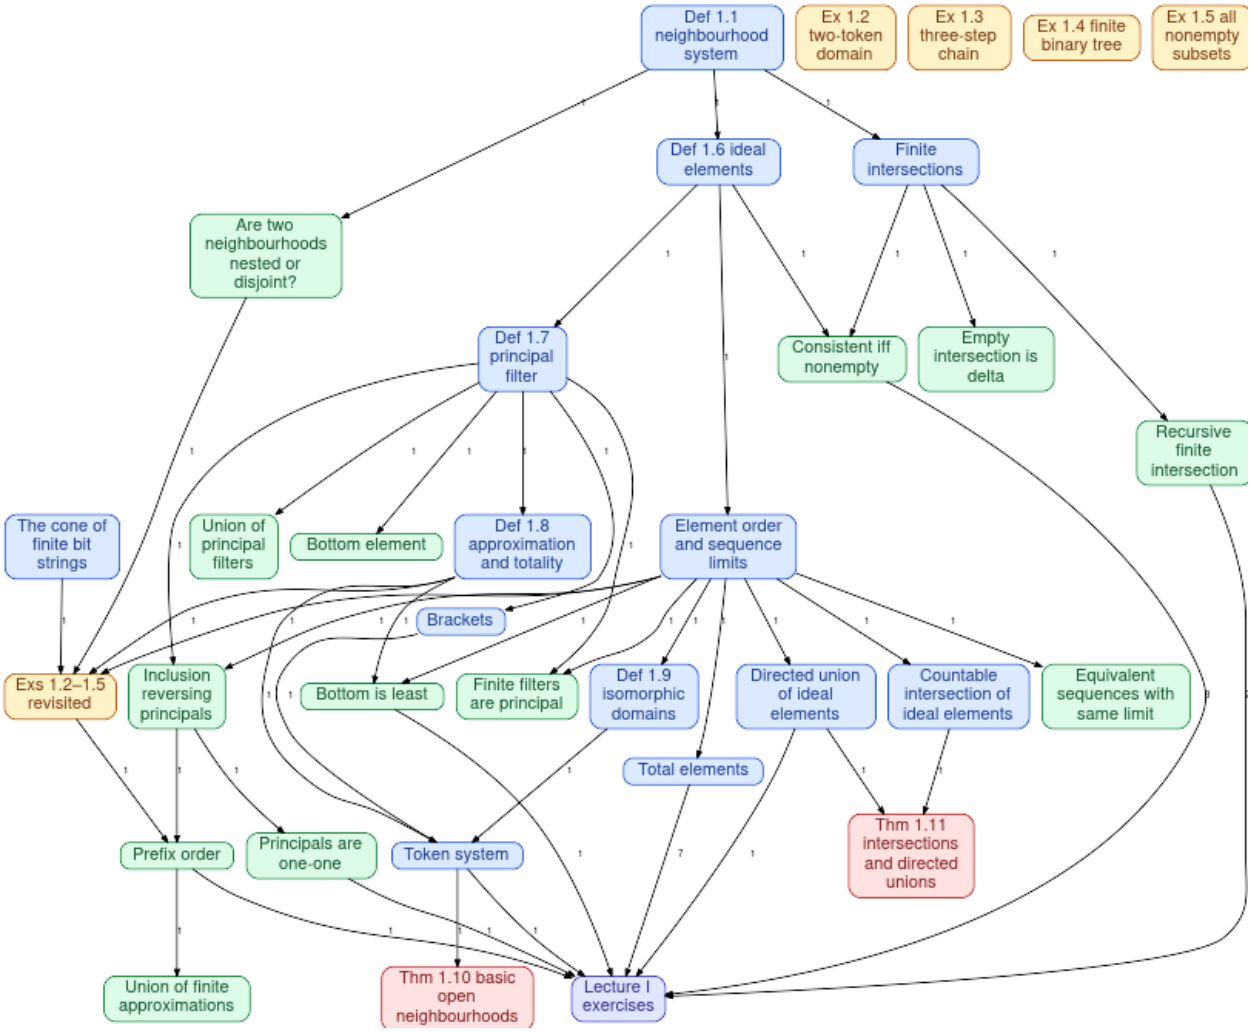

Figure 39: Diagram 7

4.2.1 Introduction

LECTURE I DOMAINS GIVEN BY NEIGHBOURHOODS

Often an object (or element) can be determined by a selection of its properties. Often it is also the case that it is easier (more convenient, more elementary) to think of these properties than it is to think of the elements themselves. Let us term the properties under consideration *neighbourhoods*, the family of those allowed a *neighbourhood system*.

Generally, the collection of these neighbourhoods is, for one reason or another, somewhat restricted; that is, a completely arbitrary property may not be allowable as a neighbourhood. Therefore, the elements determined by selections of neighbourhoods may not be as separable into the discrete objects common to the classical view of set theory. This is particularly true in working with infinite objects: it is hard to specify an infinite element completely. The theory of elements to be studied here, then, is going to permit *partial elements* as well as *total elements*, and each neighbourhood system will define a *domain* of such elements.

Since we may wish to use a neighbourhood system to introduce elements not previously investigated, the neighbourhoods do not have to be regarded as sets of the as-yet-to-be-defined objects. We can take a non-empty set Δ of *tokens* (or "traces") that function as "parts" of elements — or even as parts of "descriptions" of elements. Then a neighbourhood is a subset $X \subseteq \Delta$ containing all those tokens that provide sufficient information when taken together to "approximate" a possible element up to a certain "degree". All these words in inverted commas are vague, and in any case we shall have at the start only a *qualitative* theory of "degree of approximation". A token should be considered as a very "rough" representative of an element, and a neighbourhood should be regarded as "smoothing out" irrelevant details by grouping together *all* those representatives sharing some common feature. One neighbourhood, then, may be only a very incomplete specification of an (ideal) element; fuller specifications can be secured by taking "convergent" sequences of neighbourhoods. Even then convergence need not be to a total element.

Let us call the family of allowed neighbourhoods $\mathcal{D}$; it is a family of subsets of the set Δ. An obvious first question is: when are two neighbourhoods $X, Y \in \mathcal{D}$ neighbourhoods of the "same" element? This question of course generalizes to a (finite) sequence of neighbourhoods. This property we will call the *consistency* of the sequence of neighbourhoods. By definition this will mean that the given neighbourhoods all contain a common neighbourhood in $\mathcal{D}$. That is, for X, Y to be consistent, there must be a $Z \in \mathcal{D}$ with $Z \subseteq X$ and $Z \subseteq Y$. This is not a very informative definition, but it has something of the flavour of a notion of consistency insofar as it can be expressed within $\mathcal{D}$. When consistency holds it seems reasonable enough at first glance to say that the intersection $X \cap Y$ is also an approximation to this common element. If this is reasonable, then $X \cap Y$ should also be regarded as a neighbourhood. This assumption has many consequences, but as a preliminary theory of approximation we will find it quite workable with many natural instances. Taking intersections just means taking more and more properties of the element and putting them together "conjunctively". It is something we do all the time. We therefore accept the idea for the present for giving our first principal definition.

4.2.2 Definition 1.1 — neighbourhood system

DEFINITION 1.1. A family $\mathcal{D}$ of subsets of a given set Δ is called a *neighbourhood system* (over Δ) iff it is a non-empty family closed under the intersection of finite consistent sequences of neighbourhoods. That is to say, $\mathcal{D}$ must fulfill these two conditions:

(i) $\Delta \in \mathcal{D}$;

(ii) whenever $X, Y, Z \in \mathcal{D}$ and $Z \subseteq X \cap Y$, then $X \cap Y \in \mathcal{D}$. $\square$

Definition (`NeighborhoodSystem`). A neighbourhood system on a carrier α consists of a membership predicate on subsets of α, together with a distinguished nonempty *master* set $\Delta \subseteq \alpha$ that belongs to the system, such that every member is contained in Δ, and whenever X and Y are members and some member Z lies in $X \cap Y$, the intersection $X \cap Y$ is again a member.

Proof. This is the packaging of Scott's (i)–(ii), with the master set playing the role of Δ and the intersection clause matching the finite-consistency closure. ■

  sub_master : ∀ {X : Set α}, mem X → X ⊆ master

end DomainTheory.NeighbourhoodSystems
```

4.2.3 Finite intersections

We remark that by convention Δ corresponds to the intersection of an empty sequence of neighbourhoods.

The finite intersection of a sequence of neighbourhoods $X_0, \dots, X_{n-1}$ is defined by recursion on n: the empty intersection is the master set Δ, and each successor step intersects with the next neighbourhood.

Of course, from Definition 1.1(ii), we can extend the intersection property to any finite sequence. Consequently, we can say $X_0, \dots, X_{n-1}$ is consistent in $\mathcal{D}$ iff

$$\bigcap_{i<n} X_i \in \mathcal{D}.$$

Definition (`interUpTo`). Given a neighbourhood system $\mathcal{D}$ over Δ and a sequence X of subsets, write $\bigcap_{i<n} X_i$ for the set obtained by recursion: the empty intersection is Δ, and

$$\bigcap_{i<n+1} X_i \;=\; \Big(\bigcap_{i<n} X_i\Big) \cap X_n.$$

Definition (`Consistent`). A length-n initial segment of X is *consistent* when some member of $\mathcal{D}$ is contained in $\bigcap_{i<n} X_i$.

Theorem (`interUpTo.zero`). The empty intersection equals the master set.

Proof. Immediate from the definition. ■

Theorem (`interUpTo.succ`). The successor step peels the last factor as above.

Proof. Immediate from the definition. ■

Theorem (`interUpTo.subset`). If $j < n$, then $\bigcap_{i<n} X_i \subseteq X_j$.

Proof. By induction on n, using the successor equation and the two projections of an intersection. ■

Theorem (`interUpTo.mem`). If each X_i for $i < n$ is a member and the length-n segment is consistent, then $\bigcap_{i<n} X_i$ is a member.

Proof. By induction on n. The empty case is membership of Δ. At a successor, consistency of the longer segment yields consistency of the shorter one, so the inductive hypothesis and pairwise intersection closure finish the argument. ■

Theorem (`consistent_iff_interUpTo_mem`). If each X_i for $i < n$ is a member, then the length-n segment is consistent if and only if $\bigcap_{i<n} X_i$ is a member.

Proof. One direction is the membership theorem for finite intersections; the other takes the intersection itself as the witnessing neighbourhood. ■

Theorem (`interUpTo_antitone`). Lengthening the initial segment shrinks the finite intersection: if $j \leq k$, then $\bigcap_{i<k} X_i \subseteq \bigcap_{i<j} X_i$.

Proof. By induction on k. Equality of lengths is trivial; at a successor the longer intersection is contained in the shorter one by the left projection of an intersection. ■

    exact interUpTo.succ V X n

end NeighborhoodSystem
end DomainTheory.NeighbourhoodSystems
```

4.2.6 Element order and sequence limits

Ideal elements are ordered by reverse inclusion of neighbourhoods: $x \leq y$ when every neighbourhood of x is a neighbourhood of y. Two approximating sequences are *equivalent* when each refines the other, and the *limit family* of a sequence is the collection of all neighbourhoods that eventually contain a term of the sequence.

Definition (`element_le`). Write $x \leq y$ when every neighbourhood belonging to x also belongs to y.

Theorem (`element_le_refl`). The relation $\leq$ is reflexive.

Proof. Immediate from the definition. ■

Theorem (`element_le_trans`). The relation $\leq$ is transitive.

Proof. Compose the two neighbourhood-membership implications. ■

Theorem (`Element.ext`). Ideal elements with the same neighbourhoods are equal.

Proof. Equality of the membership predicates determines the element. ■

Theorem (`element_le_antisymm`). The relation $\leq$ is antisymmetric.

Proof. Mutual $\leq$ gives the same neighbourhoods, so the elements coincide by the preceding uniqueness. ■

Together these facts make the set of ideal elements into a partially ordered set under $\leq$.

Definition (`SeqEquiv`). Sequences X and Y of neighbourhoods are *equivalent* when for every index of either sequence some term of the other is contained in it.

Definition (`limitFamily`). The *limit family* of a sequence X is the set of all neighbourhoods Z for which some term X_n is contained in Z.

`ElementOrder.lean`

namespace DomainTheory.NeighbourhoodSystems
namespace NeighborhoodSystem

variable {α : Type*} (V : NeighborhoodSystem α)

/-- An ideal element is *total* when it is maximal in the approximation order. -/
def IsTotal (x : V.Element) : Prop := ∀ y, x ≤ y → y ≤ x

end NeighborhoodSystem
end DomainTheory.NeighbourhoodSystems
```

4.2.8 Two-token neighbourhoods

The two-token neighbourhood system on $\Delta = \{0, 1\}$.

Definition (`Token`). The token set is a two-element type, standing for $\Delta = \{0, 1\}$.

Definition (`master`). The master set is the full set of tokens.

Definition (`zero`). The singleton neighbourhood $\{0\}$.

Definition (`one`). The singleton neighbourhood $\{1\}$.

Definition (`mem`). A subset of the token set belongs to the family precisely when it equals the master set or one of the two singletons.

Theorem (`mem_iff`). A set is a neighbourhood if and only if it equals Δ, $\{0\}$, or $\{1\}$.

Proof. Immediate from the three-element family. ■

Theorem (`inter_eq`). The intersection of any two neighbourhoods is again Δ, $\{0\}$, $\{1\}$, or empty.

Proof. Case analysis on the two factors, using the absorption and disjointness facts for the master and the two singletons. ■

Definition (`neighborhoodSystem`). The neighbourhood system on the two-token carrier with this membership predicate and master set.

Proof. The master is nonempty and a neighbourhood; every neighbourhood lies in the master; if two neighbourhoods meet in a set containing a third neighbourhood, their intersection cannot be empty, so by the preceding classification it is again a neighbourhood. ■

4.2.9 Example 1.2 — two-token domain

EXAMPLE 1.2. Let $\Delta = \{0, 1\}$ and let $\mathcal{D} = \{\{0, 1\}, \{0\}, \{1\}\}$.

In pictures we have:

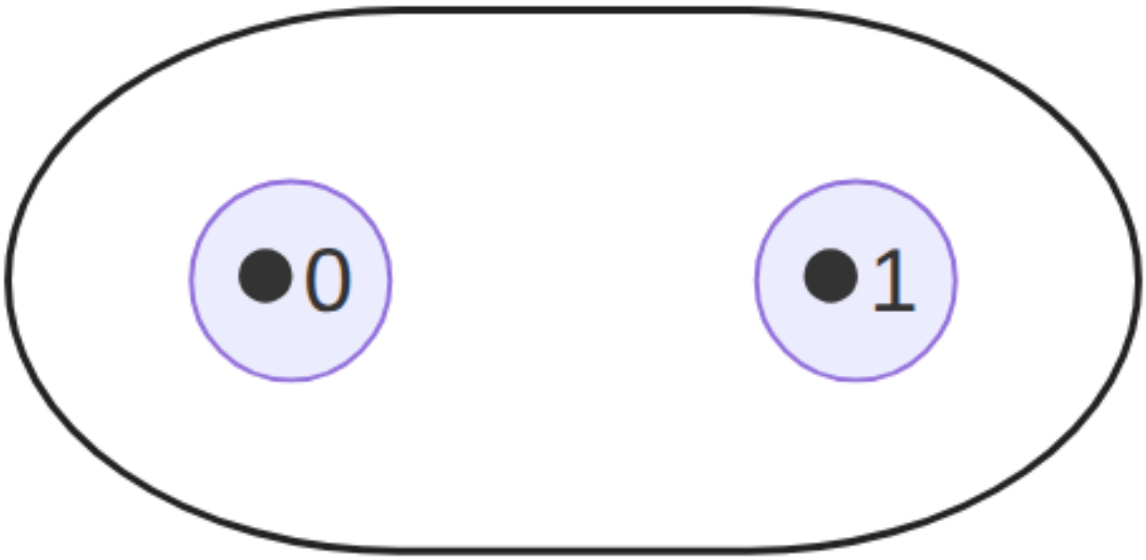

Figure 40: Example 1.2 — two-token domain.

The intention is that 0 and 1 can be completely specified and that they can be identified with the total elements. As we shall see, there is only one partial element: either we give no information (the neighbourhood $\{0,1\}$), or we decide between 0 and 1 (by giving $\{0\}$ or $\{1\}$). □

The development is with the two-token system peer.

Theorem (`example_1_2`). There is a neighbourhood system on $\{0,1\}$ whose master set is the full token set and whose neighbourhoods are exactly $\{\{0,1\},\{0\},\{1\}\}$.

Proof. By the two-token neighbourhood system. ■

```

4.2.10 Three-token neighbourhoods

The three-token nested neighbourhood system.

Definition (`Token`). The token set is a three-element type, standing for $\Delta = \{0, 1, 2\}$.

Definition (`master`). The master set is the full set of tokens.

Definition (`twelve`). The intermediate neighbourhood $\{1, 2\}$.

Definition (`two`). The singleton neighbourhood $\{2\}$.

Definition (`mem`). A subset of the token set belongs to the family precisely when it equals the master set, $\{1, 2\}$, or $\{2\}$.

Theorem (`mem_iff`). A set is a neighbourhood if and only if it equals Δ, $\{1, 2\}$, or $\{2\}$.

Proof. Immediate from the three-element family. ■

Theorem (`inter_eq`). The intersection of any two neighbourhoods is again Δ, $\{1, 2\}$, or $\{2\}$.

Proof. Case analysis on the two factors, using absorption of the master and the nesting $\{2\} \subseteq \{1, 2\}$. ■

Definition (`neighborhoodSystem`). The neighbourhood system on the three-token carrier with this membership predicate and master set.

Proof. The master is nonempty and a neighbourhood; every neighbourhood lies in the master; the intersection of any two neighbourhoods is again a neighbourhood by the preceding classification. ■

4.2.11 Example 1.3 — three-step chain

EXAMPLE 1.3. Let $\Delta = \{0, 1, 2\}$ and let $\mathcal{D} = \{\{0, 1, 2\}, \{1, 2\}, \{2\}\}$.

In pictures we have:

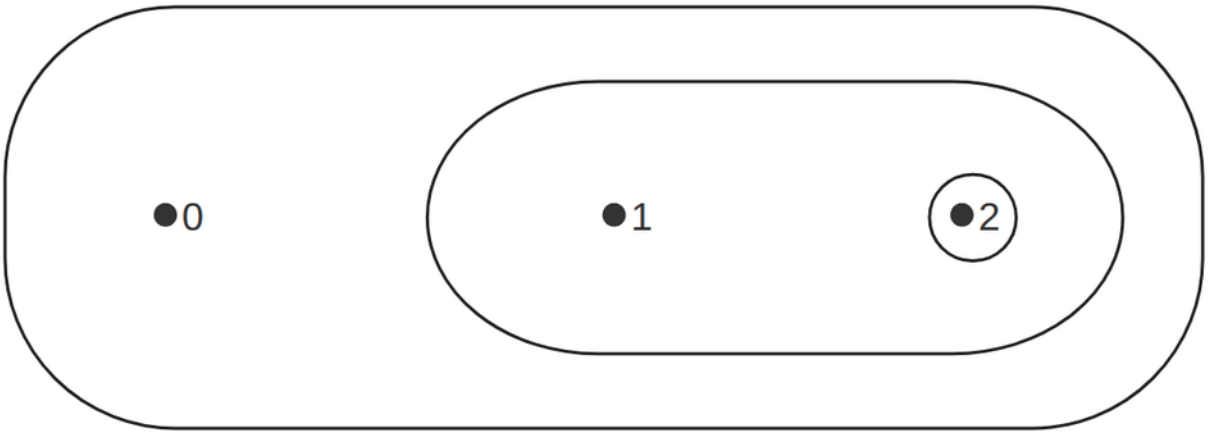

Figure 41: Example 1.3 — three-step chain.

Instead of stepping to the total element (here represented by 2) in one big step, the passage is divided into two steps. (Note 0 and 1 cannot be taken as representing total elements.) This example is not very interesting because the direction of approximation is unique. We need an example with some choice. □

The development is with the three-token system peer.

Theorem (`example_1_3`). There is a neighbourhood system on $\{0, 1, 2\}$ with master Δ and neighbourhoods Δ, $\{1, 2\}$, and $\{2\}$.

Proof. By the three-token neighbourhood system. ■

    refine (mem_iff X).trans ?_
```

```
    simp [master, two, h12]⟩
```

4.2.12 Binary-tree tokens

The finite binary-tree neighbourhood system on seven tokens.

Definition (`Token`). The token set is a seven-element type standing for $\Delta = \{\Lambda, 0, 1, 00, 01, 10, 11\}$.

Definition (`leaf00`), (`leaf01`), (`leaf10`), (`leaf11`). The four singleton neighbourhoods at the leaves of the tree.

Definition (`left`). The left-branch neighbourhood $\{0, 00, 01\}$.

Definition (`right`). The right-branch neighbourhood $\{1, 10, 11\}$.

Definition (`master`). The master set is the full set of tokens.

Definition (`mem`). A subset belongs to the family precisely when it equals the master set, the left or right branch, or one of the four leaves.

Theorem (`mem_iff`). A set is a neighbourhood if and only if it is one of those seven sets.

Proof. Immediate from the seven-element family. ■

Theorem (`not_mem_empty`). The empty set is not a neighbourhood.

Proof. Each of the seven neighbourhoods contains a distinguished token, so none equals the empty set. ■

Theorem (`inter_master`), (`master_inter`). Intersection with the master absorbs.

Proof. The master is the full token set. ■

Theorem (`left_inter_right`), (`right_inter_left`). The two branches are disjoint.

Proof. Direct membership check on the seven tokens. ■

Theorem (`left_inter_leaf00`), (`left_inter_leaf01`), (`leaf00_inter_left`), (`leaf01_inter_left`). Each left leaf sits inside the left branch.

Proof. Direct membership check on the seven tokens. ■

Theorem (`right_inter_leaf10`), (`right_inter_leaf11`), (`leaf10_inter_right`), (`leaf11_inter_right`). Each right leaf sits inside the right branch.

Proof. Direct membership check on the seven tokens. ■

Theorem (`left_inter_leaf10`), (`left_inter_leaf11`), (`leaf10_inter_left`), (`leaf11_inter_left`), (`right_inter_leaf00`), (`right_inter_leaf01`), (`leaf00_inter_right`), (`leaf01_inter_right`). A leaf of one branch misses the other branch.

Proof. Direct membership check on the seven tokens. ■

Theorem (`leaf00_inter_leaf01`), (`leaf00_inter_leaf10`), (`leaf00_inter_leaf11`), (`leaf01_inter_leaf00`), (`leaf01_inter_leaf10`), (`leaf01_inter_leaf11`), (`leaf10_inter_leaf00`), (`leaf10_inter_leaf01`), (`leaf10_inter_leaf11`), (`leaf11_inter_leaf00`), (`leaf11_inter_leaf01`), (`leaf11_inter_leaf10`). Distinct leaves are pairwise disjoint.

Proof. Direct membership check on the seven tokens. ■

Theorem (`inter_mem_or_empty`). The intersection of any two neighbourhoods is again a neighbourhood, or else empty.

Proof. Case analysis on the two factors, assembling absorption by the master, self-intersection, the branch and leaf lemmas above, and the empty intersections. ■

Definition (`neighborhoodSystem`). The neighbourhood system on this token carrier with the membership predicate and master set above.

Proof. The master is nonempty and a neighbourhood; every neighbourhood lies in the master; if two neighbourhoods meet in a set containing a third neighbourhood, their intersection cannot be empty (the empty set is not a neighbourhood), so by the preceding classification it is again a neighbourhood. ■

4.2.25 Example 1.4 — finite binary tree

EXAMPLE 1.4. Let $\Delta = \{\Lambda, 0, 1, 00, 01, 10, 11\}$ and let $\mathcal{D} = \{\Delta, \{0, 00, 01\}, \{1, 10, 11\}, \{00\}, \{01\}, \{10\}, \{11\}\}$.
Or more understandably in pictures:

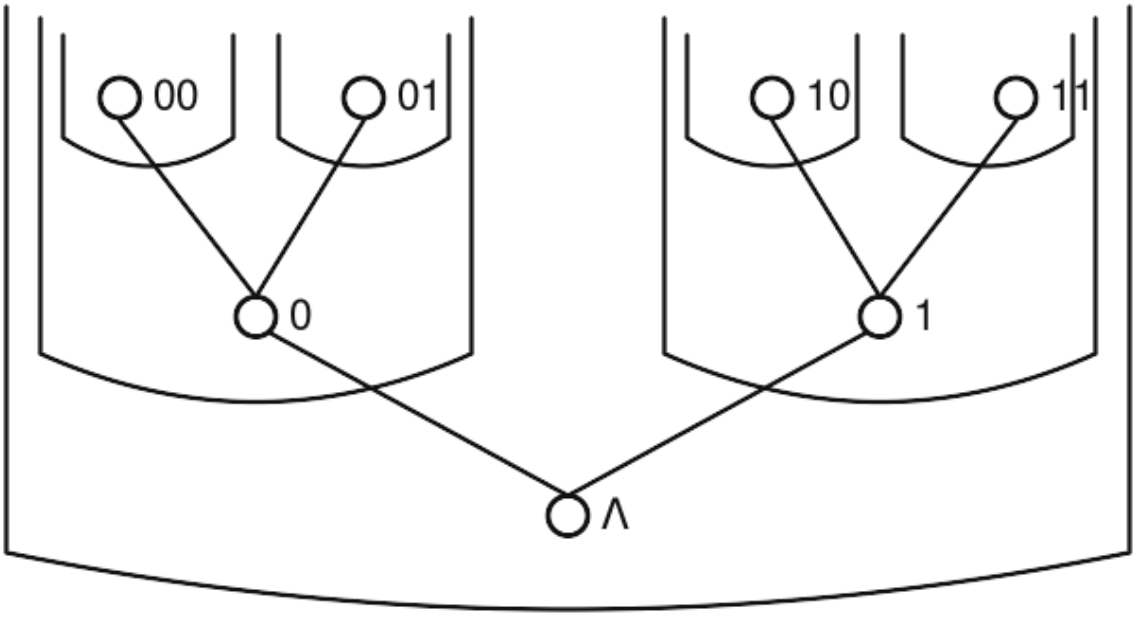

Figure 42: Binary tree of tokens with neighbourhood U-curves

The tokens are finite sequences of 0's and 1's (up to length 2) with Λ the empty sequence; they form — in the picture — the binary tree with the sequences as the nodes. The neighbourhoods are the subtrees of all nodes above a given node. Obviously this can be generalized to sequences of any length (and to trees less regular than the binary tree). The total elements of the example correspond to the top nodes 00, 01, 10, 11 and the lower nodes to the partial elements. When we are not at a top node we have only partially determined a sequence, and the branching indicates that we have some choice as to how the sequence can be extended. □

The development is with the binary-tree tokens peer.

Theorem (`example_1_4`). There is a neighbourhood system whose neighbourhoods are the listed cones and leaves of the finite binary tree.

Proof. By the binary-tree neighbourhood system. ■

`Example_1_4.lean`

```
module

public import DomainTheory.NeighbourhoodSystems.DomainsGivenByNeighbourhoods.BinTree

@[expose] public section

open DomainTheory.NeighbourhoodSystems

theorem example_1_4 :
    ∃ (V : NeighborhoodSystem Token),
      V.master = (Set.univ : Set Token) ∧
        (∀ X : Set Token,
```

```
          V.mem X ↔
            X = Set.univ ∨ X = left ∨ X = right ∨
              X = leaf00 ∨ X = leaf01 ∨ X = leaf10 ∨ X = leaf11) :=
  ⟨neighborhoodSystem, rfl, fun _ => Iff.rfl⟩
```

4.2.26 Are two neighbourhoods nested or disjoint?

It should be noted that, in these three examples, the reason that we have a neighbourhood system is a simple consequence of a very special circumstance: in these systems two neighbourhoods are either disjoint or one is included in the other. This arrangement of neighbourhoods is by no means necessary.

Definition (`NestedOrDisjoint`). A family of subsets is *nested or disjoint* when any two members X and Y satisfy $X \subseteq Y$, or $Y \subseteq X$, or else $X \cap Y = \emptyset$.

Definition (`NeighborhoodSystem.ofNestedOrDisjoint`). From a nested-or-disjoint family containing a nonempty master set Δ, with every member contained in Δ, one obtains a neighbourhood system with that membership and master.

Proof. The master hypotheses are given. For the intersection axiom: if X and Y are members and some member Z lies in $X \cap Y$, then X and Y cannot be disjoint, so one includes the other and $X \cap Y$ equals the smaller of the two, hence is again a member. ■

4.2.27 Four-token powerset

The powerset-of-four-tokens neighbourhood system (nonempty subsets).

Definition (`Token`). The token set is a four-element type, standing for $\Delta = \{0, 1, 2, 3\}$.

Definition (`P4Mem`). A subset belongs to the family precisely when it is nonempty.

Theorem (`P4_inter_mem`). If Z is nonempty and $Z \subseteq X \cap Y$, then $X \cap Y$ is nonempty.

Proof. Nonemptiness passes along the inclusion. ■

Definition (`master`). The master set is the full set of tokens.

Theorem (`P4_master_mem`), (`P4_master_nonempty`). The master is nonempty (hence a neighbourhood).

Proof. The full token set is nonempty. ■

Theorem (`P4_sub_master`). Every neighbourhood is contained in the master.

Proof. Every set of tokens lies in the full token set. ■

Definition (`neighborhoodSystem`). The neighbourhood system on the four-token carrier whose members are exactly the nonempty subsets, with this master set.

Proof. The master is nonempty and a neighbourhood; every neighbourhood lies in the master; if two neighbourhoods meet in a set containing a third neighbourhood, their intersection is nonempty by the preceding theorem, hence again a neighbourhood. ■

4.2.28 Example 1.5 — all nonempty subsets

EXAMPLE 1.5. Let $\Delta = \{0, 1, 2, 3\}$ and let $\mathcal{D}$ be the family of all non-empty subsets of Δ.

The development is with the four-token powerset peer.

Theorem (`example_1_5`). There is a neighbourhood system on four tokens whose neighbourhoods are exactly the nonempty subsets.

Proof. By the four-token neighbourhood system. ■

```

4.2.29 Consistent iff nonempty

This system is a direct generalization of Example 1.2., which was special owing to the small number of tokens. (The other examples were special by virtue of the choice of neighbourhoods.) The verification that the present $\mathcal{D}$ is a neighbourhood system rests on nothing more than the remark that sets are consistent in $\mathcal{D}$ iff they have a non-empty intersection. Clearly the arrangement of neighbourhoods in $\mathcal{D}$ can be as varied as a four-element set will allow; if Δ were made larger, the possible combinations of neighbourhoods could be made as complex as you wish. □

Theorem (`Element.mem_interUpTo`). If an ideal element belongs to each of the first n terms of a sequence of sets, then it belongs to their finite intersection $\bigcap_{i<n} X_i$.

Proof. Induction on n: the empty intersection is the master, which every ideal meets; the successor step uses that ideals are closed under pairwise intersection. ■

Theorem (`consistent_iff_inter_nonempty`). In the four-token system of all nonempty subsets, a length-n initial segment is consistent if and only if $\bigcap_{i<n} X_i$ is nonempty.

Proof. A witnessing neighbourhood below the intersection is nonempty, so the intersection is nonempty. Conversely, a nonempty intersection is itself a neighbourhood contained in itself. ■

4.2.30 Equivalent sequences with same limit

Having some idea now of the variety of neighbourhood systems, we have to discuss what it is they do. As stressed before, the tokens do not have to correspond directly to the elements; but where, we ask, do the elements come from? One obvious suggestion for determining an element is to produce a sequence of "better and better" neighbourhoods:

$$X_0 \supseteq X_1 \supseteq \cdots \supseteq X_n \supseteq \cdots$$

Trivially, any finite initial segment of this sequence is consistent, and so each X_n is a partial approximation to the "limit". If $\mathcal{D}$ were always to be taken as *finite*, of course, there would be no point in discussing limits since any such sequence would eventually be constant. The elements in the finite case would therefore be completely represented by neighbourhoods with the *minimal* neighbourhoods corresponding to the total elements. But there are many reasons to go beyond the finite (though perhaps not too far beyond).

Suppose $\langle Y_n \rangle_{n=0}^{\infty}$ is another "convergent" sequence with

$Y_{n+1} \subseteq Y_n$ for all indices: when do the two sequences of neighbourhoods determine the *same limit*? The two sequences can surely be different; for example, $\langle Y_n \rangle_{n=0}^{\infty}$ could be a subsequence of $\langle X_n \rangle_{n=0}^{\infty}$, say, $Y_n = X_{2n}$. Still we would want to say that the same limit is obtained. Without being given any further structure on the neighbourhoods, a simple answer is just to say that each sequence goes *equally deep* as the other:

for each m there is an n with $X_n \subseteq Y_m$, and

for each n there is an m with $Y_m \subseteq X_n$.

This definition obviously puts sequences into equivalence classes, and so elements could be identified with these. But such a definition is clumsy for two reasons: it is always tiresome to work with equivalence classes, and there is no reason to think that simple infinite sequences are adequate for determining elements without some rather drastic assumptions on $\mathcal{D}$. Nevertheless, the idea is *suggestive*; we just have to find some construct to represent elements in a unique way and to phrase it in a general enough manner.

Start with $\langle X_n \rangle_{n=0}^{\infty}$ again, which "converges" as before. Think of all the other sequences equivalent to this one in the sense just defined. We can define the class of all terms of all such sequences very easily as being the family:

$$x = \{Z \in \mathcal{D} \mid X_n \subseteq Z \text{ for some } n\}.$$

It is easy to prove that if we form the analogous class for $\langle Y_n \rangle_{n=0}^{\infty}$, then the two families are *equal* if and only if the sequences are *equivalent*. Thus, we seem justified in letting x represent the limit of $\langle X_n \rangle_{n=0}^{\infty}$. All we have to do now is to remark on what sort of class x is as a subfamily of $\mathcal{D}$; what we abstract from the construction, however, will be just a bit more general than taking those x that result from sequences.

Theorem (`limitFamily_eq_iff`). If every term of the sequences X and Y is a neighbourhood, then the limit families of X and of Y coincide if and only if X and Y are equivalent.

Proof. If the families agree, each term of either sequence belongs to the common family, so some term of the other sequence is contained in it. Conversely, if the sequences refine each other, a neighbourhood containing a term of one contains a (later) term of the other, so the two families are the same. ■

4.2.31 Definition 1.6 — ideal elements

DEFINITION 1.6. The (ideal) elements of a neighbourhood system $\mathcal{D}$ are those subfamilies $x \subseteq \mathcal{D}$ where:

(i) $\Delta \in x$;

(ii) $X, Y \in x$ always implies $X \cap Y \in x$; and

(iii) whenever $X \in x$ and $X \subseteq Y \in \mathcal{D}$, then $Y \in x$.

The *domain* of all such elements is written as $|\mathcal{D}|$. □

The idea of 1.6 is a well-known mathematical device: the families x satisfying (i)–(iii) are usually called *filters*. Most frequently the emphasis is put on the *maximal* filters, and these would be our *total* elements;

however, in general, the proof that maximal filters exist is non-constructive, so for our purposes it is better not to neglect the partial filters. When maximal filters can be found, well and good, but we do not have to insist on them. Note that the generality of 1.6 is achieved by not requiring that there is a sequence of neighbourhoods that "generates" the filter x. (See Exercise 1.22.)

We have often said that neighbourhoods determine partial elements by themselves; we now make this remark precise.

Definition (`Element`). An *ideal element* of a neighbourhood system is a predicate on sets that holds only of neighbourhoods, contains the master set Δ, is closed under pairwise intersection, and is upward closed among neighbourhoods: if it holds of X and Y is a neighbourhood with $X \subseteq Y$, then it holds of Y.

Proof. The four clauses match Scott's $x \subseteq \mathcal{D}$ together with (i)–(iii); the type of all such elements is the domain $|\mathcal{D}|$. ■

end NeighborhoodSystem
end DomainTheory.NeighbourhoodSystems
end
```

4.2.32 Definition 1.7 — principal filter

DEFINITION 1.7. For $X \in \mathcal{D}$, the *principal filter* determined by X is defined by:

$$\uparrow X = \{Y \in \mathcal{D} \mid X \subseteq Y\}.$$

The principal filters form what we shall call the *finite elements* of the domain $|\mathcal{D}|$. □

Definition (`principal`). For a neighbourhood X, the *principal filter* $\uparrow X$ is the ideal element whose neighbourhoods are exactly the members of $\mathcal{D}$ containing X.

Proof. Membership only for neighbourhoods containing X; the master contains X because every neighbourhood sits in Δ; pairwise intersections and upward closure among neighbourhoods are immediate from the subset relation. ■

Theorem (`mem_principal`). A set Y belongs to $\uparrow X$ if and only if Y is a neighbourhood and $X \subseteq Y$.

Proof. This is the membership clause in the definition of $\uparrow X$. ■

`principal.lean`

end

end NeighborhoodSystem
end DomainTheory.NeighbourhoodSystems
end
```

4.2.33 Inclusion reversing principals

It is obvious that the correspondence between X and $\uparrow X$ is inclusion *reversing*, in the sense that

$$X \subseteq Y \quad \text{iff} \quad \uparrow Y \subseteq \uparrow X$$

for all $X, Y \in \mathcal{D}$.

Theorem (`principal_le_iff`). For neighbourhoods X and Y, one has $\uparrow X \leq \uparrow Y$ in the approximation order if and only if $Y \subseteq X$. Equivalently, $X \subseteq Y$ if and only if $\uparrow Y \subseteq \uparrow X$ as families of neighbourhoods.

Proof. If $\uparrow X \leq \uparrow Y$, then X belongs to $\uparrow Y$, so $Y \subseteq X$. Conversely, if $Y \subseteq X$ and Z belongs to $\uparrow X$, then $X \subseteq Z$, hence $Y \subseteq Z$, so Z belongs to $\uparrow Y$. ■

```

4.2.34 Principals are one-one

It is obvious that the correspondence between X and $\uparrow X$ is one-one.

Theorem (`principal_injective`). The map sending a neighbourhood to its principal filter is injective: if $\uparrow X = \uparrow Y$, then $X = Y$.

Proof. From the inclusion-reversing equivalence, equal principals give $Y \subseteq X$ and $X \subseteq Y$. ■

4.2.35 Union of principal filters

Except in very special cases, there is much more to $|\mathcal{D}|$ than just the finite elements. Much of our investigation will be concerned with finding out how much more. The finite elements are, in a certain sense, "dense" in $|\mathcal{D}|$, however, because it is also obvious from the definitions that for each $x \in |\mathcal{D}|$

$$x = \bigcup \{\uparrow X \mid X \in x\}.$$

That is, every element is a certain type of "limit" of finite elements. (This statement is made more precise in Exercise 1.21)

We note that we have now had several occasions to use inclusion relationships between elements; this is an important relationship, and we give it a special name.

Theorem (`eq_iUnion_principal`). A neighbourhood Z belongs to an ideal element x if and only if Z belongs to $\uparrow X$ for some neighbourhood X of x. Equivalently, $x = \bigcup \{\uparrow X \mid X \in x\}$.

Proof. If Z belongs to x, take $X = Z$: then Z belongs to $\uparrow Z$. Conversely, if Z belongs to $\uparrow X$ for some neighbourhood X of x, then $X \subseteq Z$, so upward closure puts Z in x. ■

4.2.36 Definition 1.8 — approximation and totality

DEFINITION 1.8. For $x, y \in |\mathcal{D}|$, we say that x *approximates* y iff $x \subseteq y$. The element that approximates all others, $\{\Delta\}$, is called $\bot$ (read: *bottom*); it is the "least defined" element, or the "most partial" element. Elements maximal with respect to the approximation relation are called *total elements*. □

Definition (`bot`). Bottom is the principal filter of the master set: $\bot = \uparrow \Delta$.

Proof. Take the principal element determined by Δ. ■

Theorem (`mem_bot`). A set Y is a neighbourhood of $\bot$ if and only if $Y = \Delta$.

Proof. Membership in $\uparrow \Delta$ means Y is a neighbourhood containing Δ; every neighbourhood already lies in Δ, so that forces $Y = \Delta$. ■

`bot.lean`

4.2.39 Finite filters are principal

EXAMPLES 1.2 – 1.5 (Revisited). The examples as given were all finite, so any explicitly given filter x is principal, the element is finite, the minimal $X \in x$ tells us all we need to know. In such simple situations there is essentially no difference between elements and neighbourhoods — except for the reversal of the order as noted. This (necessary) reversal should not, however, become a matter of confusion: the smaller the neighbourhood has become, the more it has "converged", and so the better defined the element has become. In the approximation relation the "poorer" elements are placed below the "better" with the total up at the top. This will become clearer in discussing "infinite" elements.

Theorem (`eq_principal_of_isMin`). If X belongs to an ideal element x and is $\subseteq$-minimal among the neighbourhoods of x, then $x = \uparrow X$.

Proof. Every neighbourhood of x contains X, so belongs to $\uparrow X$; conversely every member of $\uparrow X$ is an upward extension of X and hence a neighbourhood of x. ■

Theorem (`exists_minimum_of_fintype`). When the ground set is finite, every ideal element has a $\subseteq$-minimal neighbourhood.

Proof. Among neighbourhoods of x contained in Δ, take one of least cardinality; a strictly smaller neighbourhood would contradict minimality of that cardinality. ■

Theorem (`element_eq_principal_of_fintype`). When the ground set is finite, every ideal element is principal.

Proof. Combine the previous two theorems. ■

4.2.40 The cone of finite bit strings

We let

$$\Delta = \Sigma^*,$$

where $\Sigma = \{0, 1\}$ and Σ^* means the set of all finite sequences of 0's and 1's, with Λ being the empty sequence. A neighbourhood consists of all *extensions* of a given sequence σ:

$$\sigma\Sigma^* = \{\sigma\tau \mid \tau \in \Sigma^*\}.$$

(Refer back to the finite version of 1.4.)

Definition (`Str`). Tokens are finite bit-strings: $\Sigma^* = \mathrm{List}\,\Sigma$ with $\Sigma = \{0, 1\}$.

Definition (`cone`). The cone of a string σ is $\sigma\Sigma^* = \{w \mid \sigma \text{ prefix } w\}$.

Theorem (`cone.nil`). The cone of the empty string is all of Σ^*.

Theorem (`cone.subset_cone`). One has $\sigma\Sigma^* \subseteq \tau\Sigma^*$ if and only if τ is a prefix of σ.

Theorem (`cone.trichotomy`). Any two cones are nested or disjoint.

Proof. Compare the two prefixes: one extends the other, or else no common extension exists. ■

Theorem (`cone.injective`). Equal cones come from equal strings.

Proof. Mutual inclusion of cones yields mutual prefix, hence equal length and equal strings. ■

4.2.41 Examples 1.2–1.5 (Revisited) — infinite binary neighbourhoods

EXAMPLES 1.2 – 1.5 (Revisited). The examples as given were all finite, so any explicitly given filter x is principal, the element is finite, the minimal $X \in x$ tells us all we need to know. In such simple situations there is essentially no difference between elements and neighbourhoods — except for the reversal of the order as noted. This (necessary) reversal should not, however, become a matter of confusion: the smaller the

neighbourhood has become, the more it has "converged", and so the better defined the element has become. In the approximation relation the "poorer" elements are placed below the "better" with the total up at the top. This will become clearer in discussing "infinite" elements.

Example 1.3 will be generalized in Exercise 1.12. Let us here generalize first 1.4. We let

$$\Delta = \Sigma^*,$$

where $\Sigma = \{0, 1\}$ and Σ^* means the set of all finite sequences of 0's and 1's, with Λ being the empty sequence. We write $\sigma\tau$ for the *concatenation* or *juxtaposition* of two sequences $\sigma, \tau \in \Sigma^*$. Define

$$B = \{\sigma\Sigma^* \mid \sigma \in \Sigma^*\}, \text{ where}$$

$$\sigma X = \{\sigma\tau \mid \tau \in X\},$$

for an arbitrary set $X \subseteq \Sigma^*$. In other words, a neighbourhood in B consists of all *extensions* of a given sequence σ. (Refer back to the finite version of 1.4.) We use the letter "B" to remind us of "binary", and this is an example we shall refer to many times. The proof (if it is not obvious) that B is a neighbourhood system should be done as an exercise.

What do we find in $|B|$? Of course $\bot = \{\Delta\} \in |B|$. For any $x \in |B|$ and $\sigma \in \Sigma^*$ define

$$\sigma x = \{Y \mid \sigma X \subseteq Y \text{ some } X \in x\}.$$

Definition (`memB`). Membership in B means being equal to some cone $\sigma\Sigma^*$.

Theorem (`nestedOrDisjoint`). Any two cones are nested or disjoint.

Proof. From the trichotomy of cones. ■

Definition (`B`). The binary neighbourhood system is the nested-or-disjoint system of all cones, with master $\Delta = \Sigma^*$.

Proof. Apply the nested-or-disjoint constructor, using the previous theorem and that every cone lies in Σ^*. ■

Definition (`prepend`). Prepending σ to a set X is $\sigma X = \{\sigma\tau \mid \tau \in X\}$.

Definition (`sigmaElt`). For $x \in |B|$ and $\sigma \in \Sigma^*$, the ideal element σx consists of those neighbourhoods Y for which $\sigma X \subseteq Y$ for some neighbourhood X of x.

Proof. Filter axioms follow from those of x together with the fact that prepending a cone yields a cone. ■

Definition (`sigmaBot`). Write $\sigma\ \bot$ for the principal filter of the cone $\sigma\Sigma^*$.

4.2.42 Prefix order

Again there is an exercise here to show $\sigma x \in |B|$. In particular $\sigma \perp \in |B|$ for all $\sigma \in \Sigma^*$, and these are just the finite elements. The minimal element of $\sigma \perp$ is $\sigma\Delta$. Note that $\sigma_0 \perp \subseteq \sigma_1 \perp$ if and only if σ_0 is an *initial segment* of the sequence σ_1.

Theorem (`prepend_append`). Prepending concatenates: $\sigma(\tau X) = (\sigma\tau)X$.

Proof. Expand both sides as concatenations of strings. ■

Theorem (`prepend_mono`). Prepending preserves inclusion: $X' \subseteq X$ implies $\sigma X' \subseteq \sigma X$.

Proof. Every $\sigma\tau$ with $\tau \in X'$ is likewise in σX. ■

Theorem (`prepend_univ`). Prepending the master set yields the cone: $\sigma\Delta = \sigma\Sigma^*$.

Proof. Extensions of σ are exactly concatenations $\sigma\tau$ for $\tau \in \Sigma^*$. ■

Theorem (`sigmaBot_le_iff`). One has $\sigma_0 \perp \leq \sigma_1 \perp$ if and only if σ_0 is a prefix of σ_1.

Proof. Principals compare by reverse inclusion of cones, and cones reverse-include exactly when the shorter string prefixes the longer. ■

Theorem (`sigmaElt_append`). Prepending concatenates on elements: $(\sigma\tau)x = \sigma(\tau x)$.

Proof. Unwind the definition of σx and use that prepending concatenates on sets. ■

Theorem (`sigmaElt_bot`). Prepending bottom yields the principal: $\sigma \perp = \sigma \cdot \perp$.

Proof. The only neighbourhood of $\perp$ is Δ, and $\sigma\Delta$ is the cone of σ. ■

Theorem (`sigmaElt_nil`). The empty string acts as identity: $\Lambda x = x$.

Proof. Prepending the empty string leaves sets unchanged. ■

4.2.43 Union of finite approximations

If now $x \in |B|$ is any explicitly given element (that is, if we know for any $X \in B$ whether or not $X \in x$), we have but to work out from these definitions that

$$x = \bigcup_{n=0}^{\infty} \sigma_n \perp,$$

where the $\sigma_n \in \Sigma^*$ and each σ_n is an initial segment of the next σ_{n+1}. *In general, in any domain, an element is uniquely determined by its finite approximations, and we are just making this explicit in* $|B|$. When we have complete knowledge of x, then there are two cases: either the approximations $\sigma_n \perp$ become constant from some point on (where $n > n_0$), or not. In the first case x is finite and equal to $\sigma_{n_0} \perp$; in the second case x is infinite and the σ_n fill out an infinite (one-way) sequence.

The generalization of 1.5 to the infinite case where $\Delta = \mathbf{N} = \{0, 1, 2, 3, \ldots, n, \ldots\}$ can be made in more than one way: for instance either we use as neighbourhoods *all* non-empty subsets of Δ or just those omitting but a finite number of integers. And, as will become apparent, there are other choices giving domains of quite different characters. □

Many constructions (choices of $\mathcal{D}$) lead to the "same" domain; "sameness" is an important notion and it is to be defined in terms of "isomorphism", which in turn is to be defined in terms of approximation preserving correspondences.

Theorem (`mem_iff_exists_sigmaBot`). For $x \in |B|$ and $Z \subseteq \Sigma^*$, one has $Z \in x$ if and only if there is a string σ such that $\sigma\Sigma^* \in x$ and $Z \in \sigma \perp$.

Proof. Every neighbourhood of x is some cone $\sigma\Sigma^*$, and that cone belongs to $\sigma \perp$; conversely, if a cone of x lies under Z via $\sigma \perp$, the filter axioms put Z in x. ■

This is a pointwise membership form of "x is made of finite approximations," not the displayed chain-union $x = \bigcup_n \sigma_n \perp$ along nested prefixes, nor the finite/infinite dichotomy that follows in the prose.

4.2.44 Definition 1.9 — isomorphic domains

DEFINITION 1.9. Two neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$ determine *isomorphic domains* iff there is a one-one correspondence between $|\mathcal{D}_0|$ and $|\mathcal{D}_1|$ which preserves inclusion between the elements of the domains. In symbols we write $\mathcal{D}_0 \cong \mathcal{D}_1$. □

It is certain that the property of 1.9 is necessary, but it may not be so clear that it is sufficient. We shall in fact prove in the next lecture that an isomorphism between domains always maps finite elements to finite elements, so it always results from a one-one inclusion-preserving correspondence between neighbourhoods. This is surely as strong as could be hoped. This general result is not needed to see that particular domains are isomorphic.

In some of the examples tokens corresponded to total elements and in some to partial elements; it is not difficult to see (ex post facto) that every domain can be presented with tokens exactly corresponding to partial elements.

Definition (`DomainIso`). A domain isomorphism is an order isomorphism between the posets of ideal elements of two neighbourhood systems.

Definition (`Isomorphic`). Write $\mathcal{D}_0 \cong \mathcal{D}_1$ when such a domain isomorphism exists.

Theorem (`Isomorphic.refl`). Every neighbourhood system is isomorphic to itself.

Proof. The identity order isomorphism. ■

Theorem (`Isomorphic.symm`). Isomorphism of domains is symmetric.

Proof. Invert the order isomorphism. ■

Theorem (`Isomorphic.trans`). Isomorphism of domains is transitive.

Proof. Compose the order isomorphisms. ■

4.2.45 Brackets

Given any neighbourhood system $\mathcal{D}$, define for $X \in \mathcal{D}$

$$[X] = \{x \in |\mathcal{D}| \mid X \in x\}.$$

Definition (`bracket`). The bracket of a neighbourhood X is $[X] = \{x \in |\mathcal{D}| \mid X \in x\}$.

Theorem (`mem_bracket`). An ideal element lies in $[X]$ if and only if X is one of its neighbourhoods.

Theorem (`bracket_master`). The master bracket is the whole domain: $[\Delta] = |\mathcal{D}|$.

Proof. Every ideal element contains Δ. ■

Theorem (`bracket_inter`). For neighbourhoods X and Y one has $[X] \cap [Y] = [X \cap Y]$.

Proof. Membership in both brackets means both X and Y belong to the filter, hence so does their intersection; conversely an ideal element containing $X \cap Y$ contains each factor by upward closure. ■

Theorem (`principal_mem_bracket`). The principal $\uparrow X$ lies in $[X]$.

Proof. X belongs to $\uparrow X$. ■

Theorem (`bracket_subset_iff`). For neighbourhoods X and Y, one has $[X] \subseteq [Y]$ if and only if $X \subseteq Y$.

Proof. Forward: $\uparrow X \in [X]$ forces $Y \in \uparrow X$. Reverse: upward closure of filters. ■

Theorem (`bracket_injective`). Equal brackets come from equal neighbourhoods.

Proof. Mutual inclusion of brackets yields mutual inclusion of the neighbourhoods. ■

4.2.46 Token system

The subsets $[X] \subseteq |\mathcal{D}|$ for $X \in \mathcal{D}$ form a neighbourhood system over $|\mathcal{D}|$.

Definition (`tokenSystem`). The token system of $\mathcal{D}$ is the neighbourhood system on $|\mathcal{D}|$ whose neighbourhoods are exactly the brackets $[X]$ for $X \in \mathcal{D}$, with master $|\mathcal{D}|$.

Proof. Masterhood is $[\Delta] = |\mathcal{D}|$; intersections of brackets are brackets of intersections. ■

Theorem (`tokenSystem_mem`). A set of ideal elements is a neighbourhood of the token system if and only if it equals $[X]$ for some neighbourhood X of $\mathcal{D}$.

Definition (`toToken`). Send an ideal element x of $\mathcal{D}$ to the filter of those brackets $[X]$ with $X \in x$.

Definition (`ofToken`). Send an ideal element y of the token system to the filter of those $X \in \mathcal{D}$ with $[X] \in y$.

Definition (`tokenIso`). Those two maps are mutually inverse order isomorphisms between $|\mathcal{D}|$ and the domain of the token system.

Proof. Bracket injectivity recovers neighbourhoods from brackets; order is preserved because inclusion of filters matches inclusion of brackets. ■

Theorem (`isomorphic_tokenSystem`). Every neighbourhood system is isomorphic to its token system.

Proof. The previous order isomorphism. ■

4.2.47 Theorem 1.10 — basic open neighbourhoods

THEOREM 1.10. Given any neighbourhood system $\mathcal{D}$, define for $X \in \mathcal{D}$

$$[X] = \{x \in |\mathcal{D}| \mid X \in x\}.$$

The subsets $[X] \subseteq |\mathcal{D}|$ for $X \in \mathcal{D}$ form a neighbourhood system over $|\mathcal{D}|$ which determines a domain isomorphic to $|\mathcal{D}|$.

Proof: We note first that

(1) $[\Delta] = |\mathcal{D}|$.

Next note that

(2) X, Y are consistent in $\mathcal{D}$ iff $[X] \cap [Y] \neq \emptyset$;

and that for $X, Y \in \mathcal{D}$

(3) $[X] \cap [Y] = [X \cap Y]$ if $X \cap Y \in \mathcal{D}$.

Inasmuch as

(4) $\uparrow X \in [X]$ for all $X \in \mathcal{D}$,

it easily follows that $\mathcal{D}$ and the family

$$\{[X] \mid X \in \mathcal{D}\}$$

are in a one-one, inclusion-preserving correspondence. Thus, we can induce the desired one-one correspondence between the elements of the two systems. □

The import of 1.10 is that the original tokens in Δ can be replaced by the elements of $|\mathcal{D}|$. This process replaces the neighbourhood $X \subseteq \Delta$ by the subset $[X] \subseteq |\mathcal{D}|$. As the passage is inclusion preserving, the

domain has not really changed, only its presentation. Though of some theoretical charm, the theorem is not of much use since we still have to get $\mathcal{D}$ from somewhere. It does emphasize, though, that the rôle of the tokens is simply to keep the inclusions (and intersections) of neighbourhoods sorted out. It is *not* always true that the tokens can be identified with the total elements.

The last theorem in this lecture is a result on *closure properties* of a domain with respect to set-theoretical operations which have interesting meanings with respect to approximation.

Theorem (`bracket_inter_nonempty_iff`). Neighbourhoods X and Y are consistent if and only if $[X] \cap [Y]$ is nonempty.

Proof. A common ideal element witnesses a neighbourhood under $X \cap Y$; conversely a principal of such a neighbourhood lies in both brackets. ■

Theorem (`theorem_110`). Clauses (2)–(4) of the proof, together with the token-system isomorphism, hold for every neighbourhood system.

Proof. Assemble the previous theorem with the intersection of brackets, the token-system isomorphism, and membership of principals in their brackets. (Clause (1) is the master bracket.) ■

4.2.48 Countable intersection of ideal elements

The countable intersection $\bigcap_n x_n$ of ideal elements is again an ideal element: a neighbourhood belongs to the meet precisely when it belongs to every x_n. It is the greatest lower bound of the sequence in the approximation order.

Definition (`iInter`). The countable intersection of a sequence of ideal elements is the filter of neighbourhoods belonging to every term.

Theorem (`mem_iInter`). A neighbourhood belongs to the countable intersection if and only if it belongs to every term of the sequence.

Theorem (`iInter_le`). The countable intersection is below each term of the sequence.

Proof. Membership in the meet means membership in that term. ■

Theorem (`le_iInter`). Any common lower bound of the sequence is below the countable intersection.

Proof. A neighbourhood of the bound belongs to every term, hence to the meet. ■

4.2.49 Directed union of ideal elements

Given an increasing sequence $x_0 \subseteq x_1 \subseteq \cdots$ of ideal elements, the directed union $\bigcup_n x_n$ is again an ideal element: a neighbourhood belongs to the join precisely when it belongs to some x_n. It is the least upper bound of the sequence in the approximation order. (Monotonicity is needed so that neighbourhoods drawn from different stages still have a common later stage in which their intersection may be formed.)

Definition (`iUnion`). The directed union of a monotone sequence of ideal elements is the filter of neighbourhoods belonging to some term.

Theorem (`mem_iUnion`). A neighbourhood belongs to the directed union if and only if it belongs to some term of the sequence.

Theorem (`le_iUnion`). Each term of the sequence is below the directed union.

Proof. Membership in that term witnesses membership in the join. ■

Theorem (`iUnion_le`). The directed union is below every upper bound of the sequence.

Proof. A neighbourhood of the join comes from some term, hence belongs to any common upper bound. ■

Definition (`sSupDirected`). The directed supremum of a nonempty directed family of ideal elements is the filter of neighbourhoods belonging to some member of the family.

Theorem (`le_sSupDirected`). Each member of the family is below the directed supremum.

Theorem (`sSupDirected_le`). The directed supremum is below every upper bound of the family.

Proof. As for the countable monotone case: membership in the join is witnessed by a family member. ■

4.2.50 Theorem 1.11 — intersections and directed unions

THEOREM 1.11. If $\mathcal{D}$ is a neighbourhood system and $x_n \in |\mathcal{D}|$ for $n = 0, 1, 2, \ldots$, then

(i) $\bigcap_{n=0}^{\infty} x_n \in |\mathcal{D}|$; and

(ii) $\bigcup_{n=0}^{\infty} x_n \in |\mathcal{D}|$, provided

$$x_0 \subseteq x_1 \subseteq x_2 \subseteq \cdots \subseteq x_n \subseteq x_{n+1} \subseteq \cdots .$$

Proof: The conditions of 1.6 have to be checked. For the case of intersection, all of 1.6(i)–(iii) are quite obvious. For the case of union, only 1.6(ii) gives pause and it requires the proviso. If X and Y belong to the union, then $X \in x_n$, say, and $Y \in x_m$. But, either $n < m$ or $m < n$, and if $k = \max(n, m)$, then $X, Y \in x_k$. Since $x_k \in |\mathcal{D}|$, we have $X \cap Y \in x_k$; thus, $X \cap Y$ belongs to the union. This proves (ii). □

In words, the intersection is the best element that is at the same time an approximation to all of the elements x_n; the intersection is exactly what is common to all the given elements. The union on the other hand is just what the (increasing sequence of the) x_n approximates; the union combines contributions from all the x_n into a "better" element – but no more than that.

In thinking about domains a rough diagram of the partial-ordering relation $\subseteq$ between elements is often helpful. The picture of 1.4 is an example where the nodes represent the elements. Any finite tree growing up from a root node would also be an example. Indeed, any finite partially ordered set with least element would be an example. (Here no distinction between tokens and elements is necessary.) A lattice diagram is also illustrated.

The root node is the element $\bot$ of $|\mathcal{D}|$; there need be no top node $\top$. *Approximation* is represented by a passage from a lower node to a higher node along the rising lines. The system $\mathcal{D}$ of neighbourhoods is the collection of sets each of which is all the nodes above a given node. For infinite examples, however, care must be given to introduce limit nodes. The first few exercises should be provided with pictures to illustrate the structure.

Theorem (`theorem_111`). Countable intersections of ideal elements, and directed (monotone) countable unions, are again ideal elements, characterized by pointwise membership.

Proof. Assemble the membership characterizations of the countable intersection and of the directed union. ■

4.2.51 Lecture I exercises

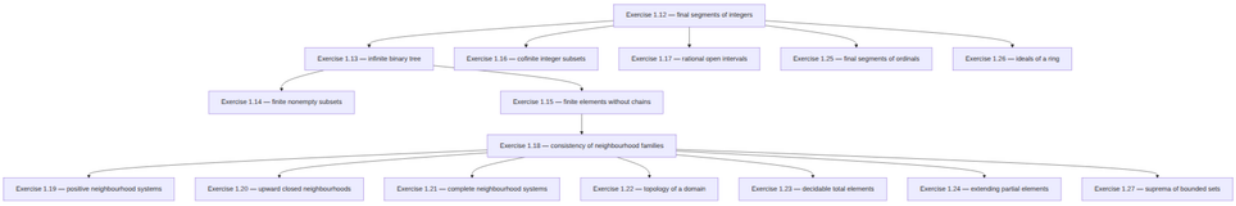

Figure 46: Lean module dependencies for Lecture I exercises.

Exercise 1.12 — final segments of integers Let $\Delta = \mathbb{N} = \{0, 1, 2, \ldots, n, \ldots\}$ be the set of non-negative integers. Use as neighbourhoods final segments:

$$\{m \in \mathbb{N} \mid m > n\}$$

for $n \in \mathbb{N}$. Verify that this is a neighbourhood system. What are the total elements? What are the finite elements? Draw a picture of the approximation relation in this domain. (Hint: there is only one limit element.)

Definition (`tail`). The final segment of threshold n is $\{m \in \mathbb{N} \mid n \leq m\}$.

Definition (`mem`). A set is a neighbourhood precisely when it equals some final segment.

Theorem (`nestedOrDisjoint`). Any two final segments are nested or disjoint (in fact nested).

Proof. Compare thresholds: the larger threshold yields the smaller segment. ■

Definition (`neighborhoodSystem`). The final-segment neighbourhood system on $\mathbb{N}$.

Definition (`fin`). The principal filter of the final segment of threshold n.

Definition (`top`). The filter of *all* final segments — the unique limit element.

Theorem (`element_eq`). Every ideal element is either some finite principal $\mathrm{fin}\, n$ or else top.

Proof. If the filter meets every final segment it is top; otherwise the least missing threshold determines a principal. ■

Theorem (`isTotal_iff_top`). An ideal element is total if and only if it equals top.

Proof. Everything approximates top, and top is maximal. ■

Theorem (`exercise_1_12`). Final segments form a nested-or-disjoint neighbourhood system, and the only total element is the limit top.

Proof. Assemble nestedness of final segments with the characterization of totality. ■

`Exercise_1_12.lean`

```
module

public import DomainTheory.NeighbourhoodSystems.DomainsGivenByNeighbourhoods.TailNat

/-- Scott's Exercise 1.12: final segments of ℕ form a neighbourhood system whose
    only total element is the limit top. -/
theorem exercise_1_12 :
    (NestedOrDisjoint mem ∧
      ∀ x : neighborhoodSystem.Element, neighborhoodSystem.IsTotal x ↔ x = top) :=
  ⟨nestedOrDisjoint, isTotal_iff_top⟩
```

Exercise 1.13 — infinite binary tree Verify all the assertions made about the system B defined as the infinite generalization of Example 1.4. Draw a picture similar to that given in the text which includes nodes for all $\sigma \in \Sigma^*$. Show the neighbourhoods, how the approximation relation behaves, and where the total elements lie. (The picture is closely related to the "binary tree", but has to have limit nodes all along the top.)

Definition (`prefixSeq`). The length-n initial segment of an infinite bit path p is the finite string $p{\restriction}n$.

Definition (`branchSeq`). The finite approximations along p are the principals $(p{\restriction}n)\ \bot$.

Theorem (`branchSeq_mono`). Along any path the sequence of principals is monotone.

Proof. Longer prefixes refine shorter ones, and principals compare by reverse inclusion of cones. ■

Definition (`branch`). The limit node of a path is the directed union of its finite approximations.

Theorem (`branch_mem_iff`). The cone of σ belongs to the branch of p if and only if σ prefixes some $p{\restriction}n$.

Proof. Unwind membership in the directed union and the characterisation of cone membership for principals. ■

Theorem (`prefix_comparable_of_mem`). If an ideal element contains both $\sigma\Sigma^*$ and $\tau\Sigma^*$, then σ and τ are prefix-comparable.

Proof. Their cones intersect in a neighbourhood, so trichotomy of cones excludes the disjoint case. ■

Theorem (`branch_isTotal`). Every infinite path yields a total element of B.

Proof. Any refinement must accept every cone already present on the branch; prefix-comparability forces those cones to lie along the same path. ■

Theorem (`exercise_1_13`). For every infinite bit path p, the corresponding branch is a total element of B.

Proof. Assemble totality of branches. ■

Exercise 1.14 — finite nonempty subsets Let $\Delta = \mathbb{N}$ and let $\mathcal{V}$ be the family of finite non-empty subsets of Δ plus the set Δ. Show that this is a neighbourhood system. What are the total elements? What are the finite elements? Draw a picture.

Definition (`mem`). A set is a neighbourhood when it is either all of $\mathbb{N}$ or a nonempty finite subset.

Definition (`neighborhoodSystem`). The neighbourhood system of finite nonempty subsets of $\mathbb{N}$ (together with the master set).

Proof of the axioms. The master set is $\mathbb{N}$. Intersections of neighbourhoods remain nonempty finite or reduce to a factor when one factor is the universe. ■

Definition (`fin`). The principal filter of a neighbourhood.

Theorem (`mem_singleton`). Every singleton is a neighbourhood.

Theorem (`singleton_isTotal`). The principal of a singleton is a total element.

Proof. Any refinement must contain that singleton; intersecting with a neighbourhood that omits the point would yield the empty set, which is not a neighbourhood. ■

Theorem (`exercise_1_14`). For every $n \in \mathbb{N}$, the principal of $\{n\}$ is total.

Proof. Assemble totality of singleton principals. ■

`Exercise_1_14.lean`

Exercise 1.15 — finite elements without chains Construct non-isomorphic infinite domains where all elements are finite but where there are no infinite chains $\langle x_n \rangle_{n=0}^{\infty}$ of elements with $x_n \sqsubseteq x_{n+1}$ but $x_n \neq x_{n+1}$ for all n.

Definition (`flatMem`). Neighbourhoods of the flat system are the universe together with the singletons.

Definition (`flat`). The flat neighbourhood system on $\mathbb{N}$.

Theorem (`flat_all_finite`). Every ideal element of the flat system is principal (hence finite).

Proof. Classify elements as bottom or a singleton principal. ■

Theorem (`flat_no_infinite_chain`). The flat system admits no strictly monotone $\mathbb{N}$-indexed chain of elements.

Proof. There is not even a strict three-element chain: atoms are maximal above bottom. ■

Definition (`stemMem`). Neighbourhoods of the stem system are the universe, the pair $\{0, 1\}$, and the singletons.

Definition (`stem`). The stem neighbourhood system on $\mathbb{N}$.

Theorem (`stem_three_chain`). The stem system has a strict three-element chain of principals.

Proof. Compare $\uparrow \Delta$, $\uparrow \{0, 1\}$, and $\uparrow \{0\}$ by reverse inclusion. ■

Theorem (`not_isomorphic`). The flat and stem domains are not isomorphic.

Proof. An isomorphism would transport the stem's three-chain into the flat domain. ■

Theorem (`exercise_1_15`). The flat and stem domains are not isomorphic — two infinite domains of finite elements, one without and one with a short strict chain.

Proof. Assemble non-isomorphism of flat and stem. ■

`Exercise_1_15.lean`

Exercise 1.16 — cofinite integer subsets Let $\Delta = \mathbf{N}$ and let $\mathcal{D}$ be the family of *cofinite* subsets of $\mathbf{N}$. Show that $|\mathcal{D}|$ is isomorphic to the partially ordered set of *all* subsets of $\mathbf{N}$ under inclusion. Construct some other neighbourhood systems where $\mathcal{D}$ is closed under finite intersection. What happens to the total elements in such systems?

Definition (`cofiniteSystem`). The neighbourhood system whose members are the cofinite subsets of $\mathbb{N}$.

Definition (`ofExcluded`). From an arbitrary set $E \subseteq \mathbb{N}$ form the filter of cofinite neighbourhoods whose complements lie in E.

Definition (`toExcluded`). From an ideal element recover the set of points whose singleton-complements belong to the filter.

Theorem (`cofiniteIso`). The map sending an ideal element to its excluded set is an order isomorphism between $|\mathcal{D}|$ and $(\mathcal{P}(\mathbb{N}), \subseteq)$.

Proof. The two constructions are mutually inverse, and approximation corresponds to inclusion of excluded sets. ■

Definition (`fullSystem`). The neighbourhood system in which every subset is a neighbourhood (closed under all intersections).

Theorem (`ofExcluded_univ_isTotal`). Excluding the whole of $\mathbb{N}$ yields a total element of the cofinite system.

Proof. Every ideal element approximates that filter. ■

Theorem (`exercise_1_16`). The cofinite system has a total element — namely the filter of all cofinite sets.

Proof. Assemble totality of the universal excluded set. ■

Exercise 1.17 — rational open intervals Let $\Delta = \mathbf{R}$ be the real line. Let $\mathcal{D}$ be the set of non-empty open intervals with rational end points plus the set Δ. Show that this is a neighbourhood system. For any real $t \in \mathbf{R}$, show that $\{X \in \mathcal{D} \mid t \in X\}$ is a filter. Is it always total? What are the total elements of $|\mathcal{D}|$? (Hint: When t is rational consider all intervals with t as a right-hand end point.)

Definition (`ratIntervalMem`). A set is a neighbourhood when it is either $\mathbb{R}$ or a nonempty open interval with rational endpoints.

Theorem (`inter_mem'`). The intersection of two neighbourhoods, when nonempty, is again a neighbourhood.

Proof. Intersecting rational open intervals yields a (possibly empty) rational open interval; nonempty intersection keeps the endpoints rational. ■

Definition (`ratIntervalSystem`). The neighbourhood system of rational open intervals on $\mathbb{R}$.

Definition (`filterAt`). For each real t, the filter of all neighbourhoods containing t.

Theorem (`filterAt_injective`). Distinct reals determine distinct point-filters.

Proof. Separate the two points by a rational open interval that contains one but not the other. ■

Theorem (`exercise_1_17`). Neighbourhoods are closed under nonempty intersection, and the point-filters separate points of $\mathbb{R}$.

Proof. Assemble the intersection lemma with injectivity of point-filters. ■

Exercise 1.18 — consistency of neighbourhood families Let $\mathcal{D}$ be a neighbourhood system. Call a subset $C \subseteq \mathcal{D}$ *consistent* iff every finite subset of C is consistent in $\mathcal{D}$. Give an example where C is a subset with more than two elements, every pair of neighbourhoods in C is consistent, but C is *not* consistent. Show that if C is consistent, then there is a *least* filter $x \in |\mathcal{D}|$ with $C \subseteq x$. Show generally that the *intersection* of any non-empty collection of filters is again a filter.

Definition (`FinitelyConsistent`). A family C of neighbourhoods is finitely consistent when every finite sequence drawn from C is consistent in $\mathcal{D}$.

Definition (`leastFilter`). From a finitely consistent family C form the least ideal element containing every member of C.

Theorem (`leastFilter_le`). Any ideal element containing all of C lies above the least filter of C.

Proof. Membership in the least filter is forced by every common upper bound. ■

Definition (`sInf`). The intersection of a nonempty family of ideal elements is again an ideal element.

Theorem (`sInf_le` / `le_sInf`). Pointwise intersection is the greatest lower bound in the approximation order.

Definition (`family`). On a three-point token set, the three pairwise-overlapping doubletons $\{0,1\}$, $\{1,2\}$, $\{0,2\}$.

Theorem (`not_finitelyConsistent`). That three-set family is pairwise nonempty but not finitely consistent.

Proof. The length-three intersection is empty, so no neighbourhood witnesses consistency of the whole family. ■

Theorem (`exercise_1_18`). Least filters of finitely consistent families are least upper bounds for those families, and the three-doubleton family is a counterexample to pairwise consistency implying finite consistency.

Proof. Assemble the least-filter inequality with the triangle counterexample. ■

      (∀ W ∈ C, z.mem W) → V.leastFilter C hCsub hC ≤ z) ∧
      ¬ system.FinitelyConsistent family :=
  ⟨NeighborhoodSystem.leastFilter_le, not_finitelyConsistent⟩
```

Exercise 1.19 — positive neighbourhood systems Define a *positive neighbourhood system* to be a family $\mathcal{D}$ where (ii) of 1.1 is replaced by **(ii')** whenever $X, Y \in \mathcal{D}$, then $X \cap Y \neq \emptyset$ iff $X \cap Y \in \mathcal{D}$. Prove that a positive neighbourhood system is indeed a neighbourhood system in the sense of the earlier definition. Give an example of a neighbourhood system that is *not* positive. (Hint: (suggested by C.A.R. Hoare). Let $\Delta = \mathbf{N} \times \mathbf{N}$, in the plane. Let $\mathcal{D}$ be the family of subsets $X \subseteq \mathbf{N} \times \mathbf{N}$ where all but a finite number of places the *vertical* sections of X are the whole of $\mathbf{N}$ but at the other places the sections are finite and nonempty. Smaller examples are of course possible.)

Definition (`IsPositive`). A neighbourhood system is positive when membership of an intersection is equivalent to nonempty intersection, for any two members.

Definition (`ofPositive`). From a positive intersection law one obtains a neighbourhood system in the sense of Definition 1.1.

Proof. Nonempty intersection of members yields a member by positivity, which discharges the witness required by the ordinary intersection axiom. ■

Definition (`notPositiveSystem`). On a three-token set, the neighbourhoods are the universe together with the doubletons $\{0, 1\}$ and $\{1, 2\}$.

Theorem (`not_isPositive`). That system is not positive.

Proof. The two doubletons meet in $\{1\}$, which is nonempty but not a neighbourhood. ■

Definition (`positiveExample`). The system of all nonempty subsets of a two-point set (built via positivity).

Theorem (`positiveExample_isPositive`). That system is positive.

Proof. Nonempty subsets are closed under nonempty intersection. ■

Theorem (`exercise_1_19`). There is a neighbourhood system that fails positivity, and there is a positive example.

Proof. Assemble the two examples. ■

Exercise 1.20 — upward closed neighbourhoods Let $\mathcal{D}$ be any neighbourhood system over a set Δ. Let $\Delta' = \mathcal{D}$ and define

$$\mathcal{D}' = \{\uparrow X \mid X \in \mathcal{D}\},$$

where

$$\uparrow X = \{Y \in \mathcal{D} \mid Y \subseteq X\}.$$

Show that $\mathcal{D}'$ is a positive neighbourhood system and that $|\mathcal{D}|$ and $|\mathcal{D}'|$ are isomorphic. Note that for $\mathcal{D}'$ finite elements and tokens are in a one-one correspondence.

Definition (`upSet`). For $X \in \mathcal{D}$, write $\uparrow X = \{Y \in \mathcal{D} \mid Y \subseteq X\}$.

Theorem (`upSet_inter`). Up-sets commute with intersection: $\uparrow X \cap \uparrow Y = \uparrow (X \cap Y)$.

Proof. Expand the definitions. ■

Definition (`powerSystem`). The neighbourhood system $\mathcal{D}'$ whose tokens are the members of $\mathcal{D}$ and whose neighbourhoods are the up-sets $\uparrow X$.

Definition (`toPower` / `ofPower`). The mutually inverse translations between ideal elements of $\mathcal{D}$ and of $\mathcal{D}'$.

Theorem (`isomorphic_powerSystem`). $|\mathcal{D}|$ and $|\mathcal{D}'|$ are isomorphic as domains.

Proof. The order isomorphism `powerIso` identifies approximation with inclusion of up-sets. ■

Theorem (`powerSystem_isPositive`). The system $\mathcal{D}'$ is positive.

Proof. Nonempty intersection of up-sets yields an up-set of an intersection of members. ■

Theorem (`toPower_principal`). Principals of $\mathcal{D}$ correspond to principals of $\mathcal{D}'$ under the isomorphism — finite elements match tokens.

Theorem (`exercise_1_20`). The power system is positive and domain-isomorphic to the original, with principals corresponding.

Proof. Assemble the isomorphism, positivity, and principal correspondence. ■

```

Exercise 1.21 — complete neighbourhood systems Work out in greater detail the proof of 1.10. Remark that the neighbourhood system over $|\mathcal{D}|$ so constructed is positive, thereby obtaining in a different way the same kind of conclusion as in 1.20. Show also that the system over $|\mathcal{D}|$ is complete in the sense that every filter is fixed by a unique member of the underlying set. (A filter is *fixed by a point* iff it is the filter of *all* neighbourhoods containing that point.) Remark that a complete system is one where tokens and (partial) elements can always be identified (under a suitable one-one correspondence). Show also that consistency of a set $\{X_i \mid i < n\}$ of neighbourhoods in $\mathcal{D}$ is equivalent to saying

$$\bigcap_{i<n} [X_i] \neq \emptyset.$$

Definition (`IsComplete`). A neighbourhood system is complete when every ideal element is the filter of all neighbourhoods containing a unique token.

Theorem (`bracket_nonempty_iff`). The bracket $[X]$ is nonempty if and only if X is a neighbourhood.

Proof. Any element of $[X]$ forces X to be a member; conversely the principal of X lies in $[X]$. ■

Theorem (`consistent_iff_iInter_bracket_nonempty`). A finite sequence of neighbourhoods is consistent if and only if the intersection of their brackets is nonempty.

Proof. Consistency is equivalent to membership of the finite intersection, hence to nonempty bracket of that intersection, which unwraps as a common point of the individual brackets. ■

Theorem (`tokenSystem_complete`). The token system over $|\mathcal{D}|$ is complete.

Proof. Each ideal element of the token system is fixed by the unique underlying element of $|\mathcal{D}|$ recovered by `ofToken`. ■

Theorem (`tokenSystem_isPositive`). The token system is positive.

Proof. Intersection of brackets is the bracket of the intersection. ■

Theorem (`tokenSystem_toToken_bijective`). Tokens of the token system biject with ideal elements of $\mathcal{D}$.

Proof. The domain isomorphism of Theorem 1.10 is bijective on underlying sets. ■

Theorem (`exercise_1_21`). Consistency is characterised by nonempty bracket intersections; the token system is complete and positive; and tokens identify with elements.

Proof. Assemble the consistency equivalences with completeness, positivity, and bijectivity of `toToken`. ■

```

Exercise 1.22 — topology of a domain (For topologists). Show that the neighbourhoods $[X]$ for $X \in \mathcal{D}$ make $|\mathcal{D}|$ into a topological space where the open subsets $\mathcal{U} \subseteq |\mathcal{D}|$ can be characterized by the following two conditions:

(i) whenever $x \in \mathcal{U}$ and $x \sqsubseteq y \in |\mathcal{D}|$, then $y \in \mathcal{U}$; and

(ii) whenever $x \in \mathcal{U}$, then $[X] \in \mathcal{U}$ for some $X \in x$.

Prove also that the inclusion relation on $|\mathcal{D}|$ can be defined topologically as:

(iii) $x \sqsubseteq y$ iff for all open $\mathcal{U} \subseteq |\mathcal{D}|$, if $x \in \mathcal{U}$ then $y \in \mathcal{U}$.

Is $|D|$ ever a Hausdorff space?

Show that if $(x_n)_{n=0}^{\infty}$ is a sequence of elements of $|D|$ with $x_n \subseteq x_{n+1}$ for all n, then

$$\bigcup_{n=0}^{\infty} x_n$$

is not only in $|D|$ but is a topological limit point of the sequence. Show that any element x is a limit point of the set $\{\uparrow X \mid X \in x\}$. Are there other limit points?

Definition (`basicOpen`). The basic open of a set X is $[X] = \{x \in |\mathcal{D}| \mid X \in x\}$.

Definition (`OpenFilter`). A set of ideal elements is open in the Scott sense when every member has a basic open neighbourhood contained in the set.

Instance (`instTopologicalSpaceElement`). Open filters form a topology on $|\mathcal{D}|$.

Proof. The universe is open via the master neighbourhood; binary intersections use pairwise intersection of neighbourhoods; arbitrary unions inherit witnesses from a component. ■

Theorem (`isOpen_basicOpen`). Every basic open is open.

Theorem (`isOpen_iff_upper_basic`). Open sets are exactly the upper sets that contain a basic open around each of their points — Scott's clauses (i) and (ii).

Proof. Unfold the open-filter definition against upward closure of filters. ■

Theorem (`le_iff_isOpen_imp`). Approximation is topological: $x \leq y$ if and only if every open containing x contains y — clause (iii).

Proof. Opens are upper; conversely test against basic opens. ■

Theorem (`specializes_iff_le`). Specialization in this topology coincides with approximation.

Theorem (`exercise_1_22`). Opens are upper basic-neighbourhood sets; basic opens are open; approximation is the open-membership order; specialization is approximation.

Proof. Assemble the preceding characterizations. ■

Exercise 1.23 — decidable total elements Suppose that the neighbourhood system D is countable, say,

$$D = \{X_0, X_1, X_2, \ldots, X_n, \ldots\}.$$

Suppose further that the property of consistency of finite sequences of neighbourhoods is decidable (or "effectively known"). Then the following sequence is well defined:

$$\begin{aligned} Y_0 &= X_0 \\ Y_{n+1} &= X_{n+1}, \text{ if this set is consistent with } Y_0, Y_1, \ldots, Y_n; \\ &= Y_n, \text{ if not.} \end{aligned}$$

Show that $\{Y_0, Y_1, \ldots, Y_n, \ldots\}$ is a total element of $|D|$. (Hint: Show first that $Y_0, Y_1, \ldots, Y_{n-1}$ is consistent for all n.) In such a system show that all filters can be determined by sequences.

Definition (`Y`). The greedy sequence that accepts the next enumerated neighbourhood precisely when it remains consistent with those already chosen.

Definition (`greedyElement`). The ideal element whose neighbourhoods are those containing some finite intersection of an initial segment of Y.

Theorem (`Y_prefix_consistent`). Every finite initial segment of Y is consistent.

Proof. By construction each accepted step preserves a nonempty witnessing intersection. ■

Theorem (`greedyElement_isTotal`). When the enumeration is surjective onto the neighbourhoods, the greedy element is total.

Proof. Any proper refinement would have to accept a neighbourhood rejected by greediness, contradicting consistency of the accumulated intersection. ■

Theorem (`filters_sequence_determined`). Every ideal element is determined by a sequence of neighbourhoods.

Proof. Enumerate those members of the enumeration that belong to the filter (or the master set otherwise). ■

Theorem (`exercise_1_23`). The greedy sequence is finitely consistent; under a surjective enumeration the greedy element is total; and every filter is sequence-determined.

Proof. Assemble the three preceding theorems. ■

Exercise 1.24 — extending partial elements (For set theorists). Prove, using the Axiom of Choice, or some equivalent principle, that in every domain a partial element can always be extended to a total element. Is this assertion equivalent to the Axiom of Choice? (Hint: Remember to prove that the union of every (transfinite) chain of filters is again a filter.)

Definition (`chainUnion`). The union of a nonempty chain of ideal elements is again an ideal element: a neighbourhood belongs to the union when it belongs to some member of the chain.

Proof. Pairwise intersection of neighbourhoods drawn from comparable chain members may be formed in the larger of the two. ■

Theorem (`le_chainUnion`). Every member of the chain approximates the chain union.

Theorem (`exists_total_ge`). Every ideal element extends to a total element.

Proof. Zorn's lemma applied to the upset of the given element: chain unions supply upper bounds. ■

Theorem (`exercise_1_24`). Every partial element extends to a total element.

Proof. Assemble the Zorn extension theorem. ■

Exercise 1.25 — final segments of ordinals (For set theorists). Let Δ be any well-ordered set (ordinal). (Even small ordinals like $\omega \cdot 3$ or ω^5 are interesting.) Let $\mathcal{D}$ be the family of non-empty *final* segments of Δ. What is $|\mathcal{D}|$? Are all elements finite? Is every approximation to a finite element finite?

Theorem (`upperSet_subset_or`). On a linear order, any two upper sets are nested.

Proof. From an element of one set missing from the other, upward closure forces the opposite inclusion. ■

Definition (`finalSegmentSystem`). The neighbourhood system of nonempty upper sets of a nonempty linear order Δ.

Theorem (`Ici_mem`). Every principal final segment $\uparrow a$ is a neighbourhood.

Theorem (`exists_Ici_of_mem`). When Δ is well-ordered, every neighbourhood equals some $\uparrow a$.

Proof. Take the least element of the neighbourhood. ■

Definition (`lowerSetOf`). The set of points a such that $\uparrow a$ belongs to the ideal element.

Definition (`ofLowerSet`). From a nonempty lower set S, the ideal element of neighbourhoods containing $\uparrow a$ for some $a \in S$.

Theorem (`finalSegmentClassify`). Ideal elements are order-isomorphic to the nonempty lower sets of Δ.

Proof. The two maps are mutually inverse once every neighbourhood is a principal final segment. ■

Definition (`topElement`). The ideal element containing every neighbourhood.

Theorem (`topElement_isTotal`). The top element is total.

Theorem (`topElement_not_principal_of_noMax`). If Δ has no greatest element, the top element is not principal.

Proof. A principal $\uparrow a$ omits every strictly later final segment. ■

Theorem (`exercise_1_25`). The top element is total, and when Δ is unbounded above it is not finite.

Proof. Assemble totality of the top with the non-principality criterion. ■

```

Exercise 1.26 — ideals of a ring (For algebraists). Let A be a commutative ring with unit. Let Δ be the set of finite subsets $F \subseteq A$. Define

$$I(F) = \{G \in \Delta \mid F \subseteq \text{the ideal generated by } G\}.$$

Prove that the sets of the form $I(F)$ form a neighbourhood system, and that the corresponding domain is isomorphic to the set of ring-theoretic ideals of A partially ordered by inclusion. What would happen if we excluded from Δ all F with $I(F) = I(\{1\})$, where 1 is the unit of A?

Definition (`IFamily`). The neighbourhood $I(F)$ consists of those finite sets whose generated ideal contains F.

Theorem (`IFamily_inter`). The intersection $I(F_1) \cap I(F_2)$ equals $I(F_1 \cup F_2)$.

Theorem (`IFamily_subset_iff`). Inclusion of neighbourhoods $I(F_1) \subseteq I(F_2)$ is equivalent to F_2 lying in the ideal generated by F_1.

Definition (`ringSystem`). The neighbourhood system of sets of the form $I(F)$ on the finite subsets of A.

Proof. Master neighbourhood $I(\emptyset)$; intersections via the union identity above. ■

Definition (`idealOf`). From an ideal element, the ring ideal of those a for which $I(\{a\})$ belongs to the filter.

Definition (`ofIdeal`). From a ring ideal J, the ideal element of those $I(F)$ with the span of F contained in J.

Theorem (`ringIso`). Ideal elements are order-isomorphic to the ring ideals of A ordered by inclusion.

Proof. The two maps are mutually inverse and preserve approximation. ■

Theorem (`IFamily_eq_of_span_eq`). Equal spans yield equal neighbourhoods $I(F)$.

Theorem (`exercise_1_26`). Equal spans of finite sets yield equal I-neighbourhoods.

Proof. The span-equality criterion for I-families. ■

  IFamily_eq_of_span_eq h
```

Exercise 1.27 — suprema of bounded sets Further closure properties of domains can be proved for bounded sets. We say $X \subseteq |\mathcal{D}|$ is *bounded* iff for some $y \in |\mathcal{D}|$ we have $x \subseteq y$ for all $x \in X$. This y is called an *upper bound*. We let

$$\bigsqcup X = \bigcap \{y \in |\mathcal{D}| \mid x \subseteq y \text{ all } x \in X\}.$$

Prove that if X is bounded, then $\bigsqcup X$ is the *least upper bound* for X in $|\mathcal{D}|$. Prove also: if $U, V \in \mathcal{D}$ are neighbourhoods, then $\{U, V\}$ is consistent in $\mathcal{D}$ iff $\{\uparrow U, \uparrow V\}$ is bounded in $|\mathcal{D}|$. (That is, boundedness is for elements what consistency is for neighbourhoods.) Prove finally with the aid of 1.18 that $X \subseteq |\mathcal{D}|$ is bounded iff every finite subset of X is bounded.

Definition (`Bounded`). A set of ideal elements is bounded when it has an upper bound under approximation.

Definition (`upperBounds`). The set of all upper bounds of a given set of ideal elements.

Definition (`sSup`). The supremum of a bounded set is the least filter of its upper bounds.

Theorem (`le_sSup`). Every member of a bounded set approximates the supremum.

Theorem (`sSup_le`). The supremum is below every upper bound.

Proof. The least-filter characterisation of the infimum of the upper bounds. ■

Definition (`pairSeq`). The length-two sequence with values U and W.

Theorem (`consistent_pair_iff_bounded`). Two neighbourhoods are consistent if and only if their principal ideal elements are bounded.

Proof. A witnessing neighbourhood for the pair intersection supplies a common principal upper bound, and conversely. ■

Theorem (`bounded_iff_finite_bounded`). A set of ideal elements is bounded if and only if every finite subset is.

Proof. The forward direction is immediate. Conversely, the neighbourhoods appearing in members of the set form a finitely consistent family by the finite-boundedness hypothesis, and the least filter of that family is an upper bound (Exercise 1.18). ■

Theorem (`exercise_1_27`). Boundedness is equivalent to finite boundedness; pairwise consistency of neighbourhoods matches boundedness of their principals; and the supremum of a bounded set is its least upper bound.

Proof. Assemble the three preceding theorems with the lub inequalities. ■

4.3 Mappings between domains

<!DOCTYPE svg PUBLIC “-//W3C//DTD SVG 1.1//EN” “http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd”>

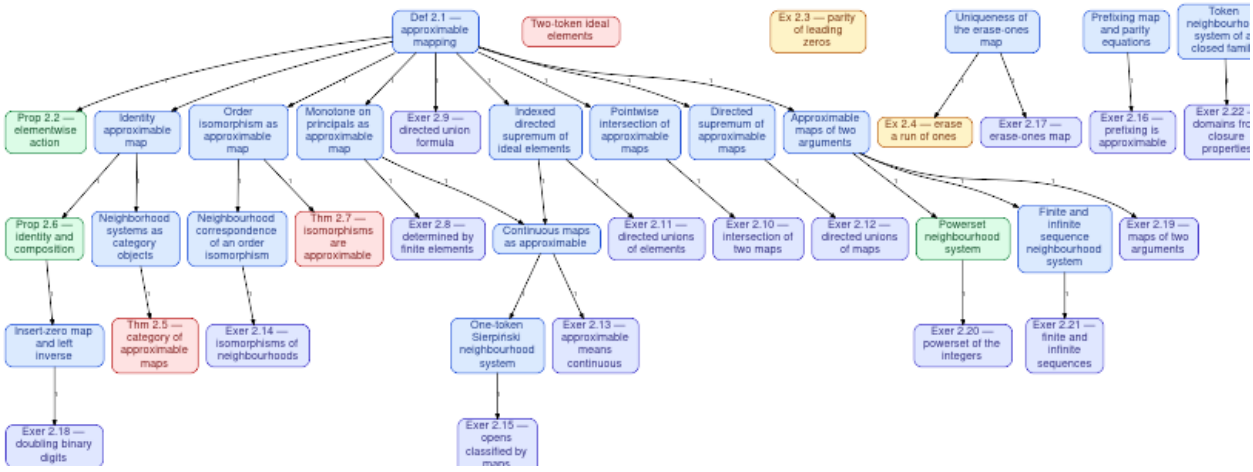

Figure 47: Diagram 12

4.3.1 Introduction

The elements of a domain are regarded as being specified by approximations: the neighbourhoods. With the idea of approximation as the dominant notion, therefore, it is natural to look for a concept of mapping (transformation of domains) that in some suitable sense preserves the spirit of the approximations. In a 'theory of computability,' where the (finite) approximations to the elements are all we can ever know at one time, the only mappings that can be computed are those that proceed by approximation, somehow passing from the neighbourhoods of one domain over to the neighbourhoods of the other.

Suppose $X \in \mathcal{D}_0$ is given - it is an approximation to certain elements of $|\mathcal{D}_0|$. (More precisely $\uparrow X$ is the approximation in the domain, but it is easier to speak of the neighbourhood X.) What can be said about the approximations of the images of these elements under the mapping we will call f? If X is not a very sharp approximation, then not very much can be said about the image in the other domain $|\mathcal{D}_1|$. Trivially, of course, we can say that Δ_1 is an approximation - because it approximates everything in its domain. Suppose, however, that we could say more. Suppose we could say that both Y and Y' approximate the image of X. If the mapping f is coherent, then it is reasonable to suppose that such a statement would imply that Y and Y' are *consistent* in $\mathcal{D}_1$. But if this is so, then since the two neighbourhoods are meant to cluster around the same images, we can feel some confidence in saying that $Y \cap Y'$ approximates these images. In other words to specify f we do not supply a unique image of X, but we say which of the $Y \in \mathcal{D}_1$ approximate the (ideal) image. To make this idea work a *monotonicity condition* is also needed since we are trying to express the idea that "if we give at least X as an approximate input to f, then we can expect at least Y as output." Thus, a mapping is taken as a kind of relation between neighbourhoods.

4.3.2 Definition 2.1 — approximable mapping

DEFINITION 2.1. An *approximable mapping* $f : D_0 \to D_1$ between domains is a binary relation $f \subseteq D_0 \times D_1$ between neighbourhoods such that

(i) $\Delta_0 f \Delta_1$;

(ii) XfY and XfY' always imply $Xf(Y \cap Y')$;

(iii) XfY, $X' \subseteq X$, and $Y \subseteq Y'$ always imply $X'fY'$. □

Condition (i) we have already discussed; in a sense it means "ask me no questions and I shall tell you no lies." In other words "zero input can expect at least zero output." The other conditions are compatible with having

$$f = \{\langle X, \Delta_1 \rangle \mid X \in D_0\};$$

that is, f might be the least informative relation and nothing more. But if it is more, then (ii) is, as we explained, a consistency condition. To explain monotonicity in (iii), suppose a mapping relationship is already known, XfY, say. If we *improve* the accuracy of X to $X' \subseteq X$ and if we *degrade* the accuracy of Y to $Y' \supseteq Y$, then we can still assert $X'fY'$ since this relationship is *less informative* than the former relationship, which was already known. Thus, we see that conditions (i)–(iii) are all reasonably argued as necessary.

One indication that the conditions of 2.1 are sufficient for a definition is that they are exactly what we need to show that f as a neighbourhood relation determines an equivalent elementwise mapping from $|D_0|$ into $|D_1|$. (Owing to the equivalence, we use the same symbol f for both.)

Definition (`ApproximableMap`). An approximable mapping between neighbourhood systems is a relation on neighbourhoods that relates the two master sets, is closed under intersection in the second argument, and is monotone under shrinking the input neighbourhood and enlarging the output neighbourhood.

Proof. The three Scott clauses are the master, intersection, and monotonicity fields; well-formedness records that related sets are neighbourhoods. ■

Theorem (`ApproximableMap.ext`). Two approximable mappings are equal when they relate the same pairs of neighbourhoods.

Definition (`ApproximableMap.toElementMap`). The elementwise action sends an ideal element x to the filter of neighbourhoods Y for which some $X \in x$ satisfies $X \; f \; Y$.

Theorem (`ApproximableMap.mem_toElementMap`). Membership in the image filter is exactly the existential formula above.

Theorem (`ApproximableMap.rel_iff_mem_principal`). The neighbourhood relation is recovered by evaluating the elementwise action at the principal filter: $X \; f \; Y$ if and only if Y belongs to $f(\uparrow X)$.

Theorem (`ApproximableMap.toElementMap_mem_iff_principal`). Membership in the elementwise image is witnessed by a principal approximation: Y belongs to $f(x)$ if and only if Y belongs to $f(\uparrow X)$ for some neighbourhood X of x.

Theorem (`ApproximableMap.ext_of_toElementMap`). Equal elementwise actions determine equal approximable mappings.

Theorem (`ApproximableMap.rel_master`). Every neighbourhood is related to the codomain master set.

Theorem (`ApproximableMap.toElementMap_mono`). The elementwise action is monotone for approximation.

4.3.3 Proposition 2.2 — elementwise action

PROPOSITION 2.2. Given neighbourhood systems D_0 and D_1, an approximable mapping $f : D_0 \to D_1$ always determines a function $f : |D_0| \to |D_1|$ between domains by virtue of the formula:

(i) $f(x) = \{Y \in D_1 \mid \exists X \in x.\ X f Y\}$

for all $x \in |D_0|$. Conversely, this function uniquely determines the original relation by the equivalence:

(ii) $X f Y$ iff $Y \in f(\uparrow X)$

for all $X \in D_0$ and $Y \in D_1$. Approximable functions are always monotone in the following sense:

(iii) $x \subseteq y$ always implies $f(x) \subseteq f(y)$,

for $x, y \in |D_0|$; moreover two approximable functions $f : D_0 \to D_1$ and $g : D_0 \to D_1$ are identical as relations iff

(iv) $f(x) = g(x)$, for all $x \in |D_0|$.

Proof: The argument that formula (i) always gives us $f(x) \in |D_1|$ when $x \in |D_0|$ can be safely left to the reader. Note, however, that all the conditions of 2.1 are required to show this. As for (ii), the implication from left to right follows directly from (i) because $X \in \uparrow X$. In the other direction $Y \in f(\uparrow X)$ means that $Z f Y$ holds for some $Z \in \uparrow X$. But from $X \subseteq Z$ it follows that $X f Y$, as we wished.

To prove monotonicity, assume $x \subseteq y$. Now $X \in x$ and $X f Y$ always imply $X \in y$ and $X f Y$. This means $Y \in f(x)$ always implies $Y \in f(y)$; that is, $f(x) \subseteq f(y)$.

Finally, to check that (iv) means $f = g$ as relations, all that has to be remarked that this follows from formulae (i) and (ii). □

Note that the right-hand side of (ii) can be written:

$$\uparrow Y \subseteq f(\uparrow X),$$

which can be read as saying that the partial element determined by the neighbourhood Y approximates the function value at the element determined by X. This precise relationship of course fits the informal discussion of mapping given earlier. Indeed whenever $x \in [X]$ and $X f Y$ hold, then $f(x) \in [Y]$ always follows, which is another way to construe the mapping character of f. Some examples of mappings are now called for.

Theorem (`ApproximableMap.mem_toElementMap`). Membership in the elementwise image is the existential formula of clause (i).

Theorem (`ApproximableMap.rel_iff_mem_principal`). The neighbourhood relation is recovered by evaluating at the principal filter (clause (ii)).

Theorem (`ApproximableMap.toElementMap_mono`). The elementwise action is monotone for approximation (clause (iii)).

Theorem (`ApproximableMap.ext_of_toElementMap`). Equal elementwise actions determine equal relations (clause (iv)).

Theorem (`proposition_2_2`). Approximable maps act elementwise; the action recovers the relation on principals; it is monotone; and equal actions determine equal relations.

Proof. Assemble the four preceding theorems. ■

4.3.4 Two-token ideal elements

Ideal elements of the two-token neighbourhood system of Example 1.2: the unique partial element $\bot$, the two totals determined by $\{0\}$ and $\{1\}$, and the classification and order facts among them.

Definition (`bot`). The least ideal element: the filter consisting of the master neighbourhood alone.

Definition (`elemOne`). The principal filter of the neighbourhood $\{1\}$.

Theorem (`zero_not_subset_one`). The singleton $\{0\}$ is not contained in $\{1\}$.

Definition (`elemZero`). The principal filter of the neighbourhood $\{0\}$.

Theorem (`zero_ne_master`). The singleton $\{0\}$ is not the master set.

Theorem (`one_ne_master`). The singleton $\{1\}$ is not the master set.

Theorem (`mem_zero_of_mem`). Any ideal element containing $\{0\}$ equals the principal of $\{0\}$.

Theorem (`mem_one_of_mem`). Any ideal element containing $\{1\}$ equals the principal of $\{1\}$.

Theorem (`zero_ne_one`). The singletons $\{0\}$ and $\{1\}$ are distinct.

Theorem (`bot_lt_elemOne`). The bottom element strictly approximates the principal of $\{1\}$.

Theorem (`bot_lt_elemZero`). The bottom element strictly approximates the principal of $\{0\}$.

Theorem (`element_classification`). Every ideal element is bottom, the principal of $\{0\}$, or the principal of $\{1\}$.

Proof. Case on membership of the two singletons; otherwise only the master remains. ■

Theorem (`bot_is_unique_partial`). Bottom is the unique element that is neither principal of $\{0\}$ nor of $\{1\}$.

Theorem (`not_elemOne_le_elemZero`). The principal of $\{1\}$ does not approximate the principal of $\{0\}$.

Theorem (`not_elemZero_le_elemOne`). The principal of $\{0\}$ does not approximate the principal of $\{1\}$.

Theorem (`eq_bot_of_le_elemZero_of_le_elemOne`). Anything below both totals is bottom.

4.3.5 Parity scan into truth

Parity of leading zeros before the first one, as an approximable map from the binary-tree system into the two-token truth domain.

Definition (`T`). The two-token neighbourhood system of Example 1.2, used as the output domain.

Definition (`botElt`). The undefined element of $|T|$.

Theorem (`botElt_le`). Undefined approximates every element of $|T|$.

Definition (`falseElt`). The total element of $|T|$ standing for a negative outcome.

Definition (`scan`). Reading a finite binary string left to right, return the parity of the number of leading zeros before the first one, or undefined if no one appears.

Theorem (`scan_nil`). The empty string scans to undefined.

Theorem (`scan_true`). A string beginning with one scans to true (even parity of leading zeros).

Theorem (`scan_false`). A leading zero flips the scanned parity of the remainder.

Theorem (`scan_append`). Once a string has a definite scan value, appending any suffix leaves that value unchanged.

Definition (`trueElt`). The total element of $|T|$ standing for a positive outcome.

Definition (`valElt`). Interpret an optional boolean as undefined, true, or false in $|T|$.

Theorem (`valElt_scan_mono`). Extending a string can only refine the scanned value in the approximation order.

Definition (`parityMap`). The approximable mapping from the binary-tree system to T that relates a cone on σ to a neighbourhood belonging to the scanned value of σ.

Proof. Master, intersection, and monotonicity follow from the corresponding properties of ideal elements and the scan-extension lemma. ■

Theorem (`eq_botElt_of_le`). Anything below both true and false is undefined.

Theorem (`parityMap_rel_cone`). On cones, the relation is exactly membership of the scanned value.

Theorem (`parityMap_toElementMap_mem`). The elementwise action holds of Y precisely when some cone in the input element scans to a value containing Y.

Theorem (`parityMap_toElementMap_sigmaElt`). After a fixed prefix σ, the elementwise action on σx is scanning σ concatenated with a cone from x.

Theorem (`scan_append_falseFalse`). Two leading zeros leave the scan of the remainder unchanged.

Theorem (`scan_append_falseTrue`). A leading zero followed by a one scans to false.

Theorem (`scan_append_true`). A leading one scans to true regardless of the rest.

4.3.6 Example 2.3 — parity of leading zeros

EXAMPLE 2.3. Let T be the neighbourhood system of the two-token domain of Example 1.2. To avoid confusion with some other domains, we will call the two total elements of $|T|$ respectively true and false. There is only one other finite element here, namely $\perp =$ undefined. We often use these elements as indicators of results: true indicates a positive outcome; false, a negative outcome; and $\perp$ indicates that there is not enough information to decide the outcome totally.

Let B be the system for the binary tree as in the last chapter. What we wish to define is an approximable mapping $f : B \to T$. The intuitive idea of the mapping we have in mind is that the binary sequence is being read from left to right, and we are counting the number of 0's seen before the first 1 is encountered. We then test the parity of this count; if it is even, the output is true; if not, false. Using a suggestive informal notation with three dots, some results of the function that does the counting and testing can be written as:

$$f(0000101\ldots) = \text{true}$$
$$f(1101110\ldots) = \text{true}$$
$$f(0111011\ldots) = \text{false}$$
$$f(0000000\ldots) = \perp .$$

The last equation is necessary, because 0000000 as a partial element cannot be counted as either even or odd since it can have inconsistent extensions:

$$0000000\ \perp \sqsubseteq 00000001\ \perp$$
$$0000000\ \perp \sqsubseteq 000000000001\ \perp .$$

So, as far as f is concerned, a plain string of 0's is indefinite. The same answer holds if the 0's go on infinitely.

To be more precise we want

$$f(0^n 1\ \perp) = \text{true} \quad \text{if } n \text{ is even;}$$
$$= \text{false} \quad \text{if } n \text{ is odd.}$$

As a binary relation $f \subseteq B \times T$ we will have

$X f Y$ iff $Y \in \perp$ or $X \sqsubseteq 0^n 1\Delta$ for some $n \in \mathbf{N}$ and either n is even and $Y \in$ true or n is odd and $Y \in$ false.

It should be checked that 2.1(i)–(ii) are satisfied. □

The development is with the parity scan into truth peer.

Theorem (`example_2_3`). Scanning two leading zeros leaves the scan of the remainder unchanged; a leading zero followed by a one scans to false; a leading one scans to true.

Proof. By the scan lemmas of the truth peer. ■

parity map into the two-token truth domain. -/
theorem example_2_3 :
    (∀ τ, scan ([false, false] ++ τ) = scan τ) ∧
    (∀ τ, scan ([false, true] ++ τ) = some false) ∧
    (∀ τ, scan ([true] ++ τ) = some true) :=
  ⟨scan_append_falseFalse, scan_append_falseTrue, scan_append_true⟩
```

4.3.7 Erase a run of ones

Erase the first consecutive run of ones on the binary-tree system.

Definition (`SatisfiesRunEquations`). An approximable endomap of the binary-tree system satisfies the run equations when it intertwines a leading zero with the image, collapses two leading ones to one, sends a leading one-zero to a leading zero, and sends a lone leading one on bottom to bottom.

Definition (`del`). Erase a leading run of ones from a string, leaving a leading zero or the empty string.

Theorem (`del_nil`). Erasing ones from the empty string yields empty.

Theorem (`del_true`). Erasing ones after a leading one continues on the tail.

Theorem (`del_false`). A leading zero is left intact by the erase-ones string map.

Definition (`out`). Erase the first run of ones in a string, copying zeros and deleting a leading run of ones via the delete map.

Theorem (`out_nil`). The erase-ones string map sends empty to empty.

Theorem (`out_false`). A leading zero is preserved and the remainder is erased recursively.

Theorem (`out_true`). A leading one is deleted by the delete map on the tail.

Theorem (`del_append`). Deleting ones is monotone for string prefix.

Proof. Induction on the prefix. ■

Theorem (`out_append`). The erase-ones string map is monotone for string prefix.

Proof. Induction, using monotonicity of the delete map on a leading one. ■

Theorem (`out_mono`). Prefix-comparable strings have erase-ones images that remain prefix-comparable.

Proof. Unpack the prefix witness and apply the append form. ■

Definition (`runMap`). The approximable mapping on the binary-tree system that relates a cone on σ to neighbourhoods containing the cone on the string obtained by erasing the first run of ones in σ.

Proof. Master, intersection, and monotonicity follow from injectivity of cones and monotonicity of the erase-ones string map. ■

Theorem (`out_append_false`). Erasing ones after a leading zero yields a leading zero followed by the erased remainder.

Theorem (`out_append_trueFalse`). A leading one followed by a zero erases to that zero and the rest of the string.

Theorem (`out_append_trueTrue`). Two leading ones erase the same as a single leading one followed by the same tail.

Theorem (`out_true_false`). Cons form of the one-then-zero case.

Theorem (`out_true_true`). Cons form of the two-ones case.

Theorem (`key`). Any approximable map satisfying the run equations acts on finite approximations $\sigma\ \bot$ by the erase-ones string map.

Proof. Induction on σ, using the run equations at each of the empty, lone-one, one-zero, two-ones, and leading-zero cases, together with the string identities above. ■

Theorem (`runMap_rel_cone`). On cones, the relation is membership of a neighbourhood containing the erased output cone.

4.3.8 Example 2.4 — erase a run of ones

EXAMPLE 2.4. Let us briefly describe an approximable mapping $g : B \to B$. Informally, g can be said to "read a sequence from left to right and eliminate the first consecutive run of 1's while copying all the other digits as read." We will have

$$g(0^n 1^k 0x) = 0^{n+1}x$$

provided $k > 0$. (Here 1^k means a string of 1's of length k.) However, if 1^∞ is the infinite sequences of 1's, then

$$g(1^\infty) = \bot, \text{ and}$$
$$g(0^n 1^\infty) = 0^n.$$

This example is instructive, since it shows that a non-trivial mapping can transform a total element into a partial element. □

Aside from our being able to define particular functions outright, we can combine functions in many different ways; the idea of composition is probably the most basic scheme of combination, and there is a technical name for a family of structures with mappings that can be so combined.

The development is with the erase a run of ones peer.

Theorem (`example_2_4`). Erasing a leading zero, a leading one-zero, or two leading ones behaves as for the erase-ones string map, and the approximable endomap of the binary-tree system satisfies the run equations.

Proof. By the string identities and the run-equation witness of the erase-ones peer. ■

4.3.9 Identity approximable map

The identity approximable map on a neighbourhood system, composition of approximable maps, and the category laws (units and associativity).

Definition (`idMap`). The identity approximable map on a neighbourhood system relates neighbourhoods X and Y precisely when $X \subseteq Y$.

Proof. Master, intersection, and monotonicity are immediate from the corresponding properties of neighbourhoods and inclusion. ■

Theorem (`idMap_rel`). The relation of the identity map is membership of both arguments together with inclusion.

Definition (`comp`). The composition of approximable maps relates X to Z when some intermediate neighbourhood Y is related by the first map to X and by the second to Z.

Proof. Master uses the two master relations; intersection and monotonicity follow by intersecting or shrinking the intermediate neighbourhoods via the component maps. ■

Theorem (`comp_rel`). Composition relates X to Z if and only if such an intermediate neighbourhood exists.

Theorem (`toElementMap_idMap`). The elementwise action of the identity map is the identity on ideal elements.

Proof. A neighbourhood of the image comes from a smaller neighbourhood of the input by upward closure; conversely the input neighbourhood itself witnesses the relation. ■

Theorem (`toElementMap_comp`). The elementwise action of a composite is the composite of the elementwise actions.

Proof. Reassociate the witnessing intermediate neighbourhoods. ■

Theorem (`commute_apply`). If two endo-maps commute under composition, their elementwise actions commute.

Proof. Apply the preceding theorem to both composites. ■

Theorem (`comp_assoc`). Composition of approximable maps is associative.

Proof. Reassociate the witnessing intermediate neighbourhoods. ■

Theorem (`comp_idMap`). Composing on the right with the identity leaves a map unchanged.

Proof. An intermediate neighbourhood related by identity is a supersets of the input, so monotonicity recovers the original relation, and conversely the input neighbourhood itself serves as intermediate. ■

Theorem (`idMap_comp`). Composing on the left with the identity leaves a map unchanged.

Proof. Dual to the right-unit law: the intermediate neighbourhood may be taken to be the output neighbourhood. ■

4.3.10 Neighborhood systems as category objects

Bundle neighbourhood systems as objects of the category whose morphisms are approximable maps.

Definition (`DomainObj`). A *domain object* is a token type together with a neighbourhood system on that type. (The name records the category-theoretic rôle: such a bundle is an object of the category below. The neighbourhood system itself is the presentation; the domain of ideal elements is $|D|$.)

Definition (`instCategoryDomainObj`). Neighbourhood systems and approximable mappings form a category: morphisms are approximable maps between the underlying systems; the identity morphism is the identity approximable map; composition of morphisms is composition of approximable maps (in diagrammatic order). The unit and associativity laws are those already proved for identity and composition of approximable maps.

Proof. Immediate from the corresponding facts for the identity map and composition. ■

Theorem (`DomainObj.id_val`). The identity morphism on a domain object is the identity approximable map of its neighbourhood system.

Theorem (`DomainObj.comp_val`). Composition of morphisms of domain objects is composition of the underlying approximable maps.

4.3.11 Theorem 2.5 — category of approximable maps

THEOREM 2.5. The class of neighbourhood systems and approximable mappings form a *category*, where the identity mapping $I_D : D \to D$ relates $X, Y \in D$ as follows:

(i) $X\ I_D\ Y$ iff $X \subseteq Y$.

If $f : D_0 \to D_1$ and $g : D_1 \to D_2$ are given, then the *composition* $g \circ f : D_0 \to D_2$ relates $X \in D_0$ and $Z \in D_2$ as follows:

(ii) $X\ g \circ f\ Z$ iff $\exists Y \in D_1.\ X\ f\ Y$ and $Y\ g\ Z$.

Proof: (We may use [41] as the standard reference on category theory, but we require hardly more than the basic definitions at this stage.) To check that we have a category, we need to know that the identity and composition maps really are maps in the category and that certain identity and associative laws hold. Now it is obvious that I_D satisfies 2.1 (i)-(iii). Moreover if $f : D_0 \to D_1$, all we have to prove is:

$$f \circ I_{D_0} = I_{D_1} \circ f = f$$

Checking one of these equations is enough. Thus, for $X \in D_0$ and $Z \in D_1$ we find

$$\begin{aligned} X\ f \circ I_{D_0}\ Z &\text{ iff } \exists Y \in D_0.\ X \subseteq Y \text{ and } Y\ f\ Z \\ &\text{iff } X\ f\ Z. \end{aligned}$$

So, f and $f \circ I_{D_0}$ are the same mapping.

Suppose now that $f : D_0 \to D_1$ and $g : D_1 \to D_2$. We have to verify that $g \circ f$ is an approximable mapping. First off, there is no trouble in seeing that $\Delta_0\ g \circ f\ \Delta_2$ holds. Next, suppose that $X\ g \circ f\ Z$ and $X\ g \circ f\ Z'$ hold. Then we have $X\ f\ Y$ and $Y\ g\ Z$ for some choice of $Y \in D_1$. Also $X\ f\ Y'$ and $Y'\ g\ Z'$ hold for some choice of $Y' \in D_1$. By 2.1 (ii) it follows that $X\ f\ (Y \cap Y')$. Since $Y \cap Y' \subseteq Y$, we conclude $(Y \cap Y')\ g\ Z$ by 2.1 (iii); similarly $(Y \cap Y')\ g\ Z'$. Invoking 2.1 (ii) again, we obtain $(Y \cap Y')\ g\ (Z \cap Z')$, and $X\ g \circ f\ (Z \cap Z')$ is proved.

Suppose finally that $X' \subseteq X$, $X\ g \circ f\ Z$, and $Z \subseteq Z'$. Now $X\ f\ Y$ and $Y\ g\ Z$ for some $Y \in D_1$. But then $X'\ f\ Y$ holds; for a similar reason $Y\ g\ Z'$ holds also. Therefore, $X'\ g \circ f\ Z'$ is established, which means that we have checked 2.1 (iii) for $g \circ f$ and have completed the proof that $g \circ f : D_0 \to D_2$.

The verification of associativity is a purely logical deduction. Thus suppose that in addition to f and g we have $h : D_2 \to D_3$. If $X \in D_0$ and $W \in D_3$ we find

$$
\begin{aligned}
X\ h \circ (g \circ f)\ W \text{ iff } & \exists Z \in D_2.\ X\ g \circ f\ Z \text{ and } Z\ h\ W \\
\text{iff } & \exists Z \in D_2\ \exists Y \in D_1.\ X\ f\ Y \text{ and } Y\ g\ Z \text{ and } Z\ h\ W \\
\text{iff } & \exists Y \in D_1\ \exists Z \in D_2.\ X\ f\ Y \text{ and } Y\ g\ Z \text{ and } Z\ h\ W \\
\text{iff } & \exists Y \in D_1.\ X\ f\ Y \text{ and } Y\ (h \circ g)\ W \\
\text{iff } & X\ (h \circ g) \circ f\ W.
\end{aligned}
$$

So, as relations, $h \circ (g \circ f) = (h \circ g) \circ f$. □

Theorem (`theorem_2_5`). Neighbourhood systems and approximable maps form a category: the identity relates neighbourhoods by inclusion (among members of the system); composition is existential mediation by an intermediate neighbourhood; and the identity and associativity laws hold for morphisms of bundled neighbourhood systems.

Proof. The relational characterizations are those of the identity map and of composition; the unit and associativity laws are the corresponding laws of the category of neighbourhood systems. ■

4.3.12 Proposition 2.6 — identity and composition

It may seem as though we have, in the definition of composition, written things backwards. But the reason is that when mappings are taken as elementwise functions, then the order is preserved in expressions involving the usual function value notation. We have, for example:

PROPOSITION 2.6. Given $f : D_0 \to D_1$ and $g : D_1 \to D_2$, the following equations hold:

(i) $I_{D_0}(x) = x$, and

(ii) $(g \circ f)(x) = g(f(x))$,

for all $x \in |D_0|$. □

The proof is not troublesome and is left as an exercise. In technical language the result shows that the category defined in Theorem 2.5 is equivalent to a "concrete category" of sets and functions, namely the domains and elementwise transformations of 2.2.

Toward the end of the last lecture (see 1.9) we promised to show that isomorphisms of domains always come from approximable mappings, and this we now do. It means that the category contains all the isomorphisms it should have.

Theorem (`proposition_2_6`). The identity approximable map acts as the identity on ideal elements, and the elementwise action of a composite is the composite of the elementwise actions.

Proof. Assemble the corresponding facts for the identity map and for composition. ■

4.3.13 Order isomorphism as approximable map

The approximable map induced by an order isomorphism of ideal elements, recovering the isomorphism elementwise, and sending principal filters to principal filters.

Definition (`ofIso`). An order isomorphism of ideal elements induces an approximable map: a neighbourhood X relates to Y when Y belongs to the image of the principal filter of X.

Proof. Domain and codomain membership are immediate; the master relation uses the two masters; intersection and monotonicity follow from the corresponding properties of the image filter and monotonicity of the isomorphism. ■

Theorem (`exists_principal_eq_apply_principal`). An order isomorphism of ideal elements sends each principal filter to a principal filter.

Proof. Form the directed family of preimages of principals below the image of the given principal; its directed supremum recovers that principal, and membership of the original neighbourhood yields a principal that equals the image. ■

Theorem (`toElementMap_ofIso`). The elementwise action of the induced map is the original isomorphism.

Proof. One inequality is monotonicity on principals; the reverse uses the inverse isomorphism and the defining relation. ■

Theorem (`exists_approximable_of_iso`). Every order isomorphism of ideal elements arises as the elementwise action of some approximable map.

Proof. Take the induced map and the preceding recovery theorem. ■

4.3.14 Theorem 2.7 — isomorphisms are approximable

THEOREM 2.7. Every isomorphism between domains results from an approximable mapping between the neighbourhood systems. Moreover, finite elements are always transformed into finite elements.

Proof: Suppose that $f : |D_0| \to |D_1|$ is a one-one, inclusion-preserving function defined on elements, where the range of the function is the whole of $|D_1|$, of course. Taking the hint from 2.2, there is only one way we could define a neighbourhood mapping; namely, we consider the relation $Y \in f(\uparrow X)$ for $X \in D_0$ and $Y \in D_1$. What has to be shown is that this is an approximable mapping which determines the original function via the formula 2.2 (i).

The first part is easy; indeed, there is a general result that monotone functions on finite elements of one domain to arbitrary elements of another domain always determine approximable mappings (cf. Exercise

2.8). What remains, then, is to show that the relation re-defines the function. This comes down to showing that for $x \in |D_0|$

$$f(x) = \{Y \in D_1 \mid \exists X \in x.\, Y \in f(\uparrow X)\}.$$

Consider the right-hand side of this equation: it is a filter. (This either can be proved directly or Exercise 2.11 can be used.) Because f is an onto-function, we can call the right-hand side $f(x')$ for some $x' \in |D_0|$. But since $X \in x$ implies $\uparrow X \subseteq x$ and $f(\uparrow X) \subseteq f(x)$, the right-hand side is included in the left-hand side. In other words $f(x') \subseteq f(x)$. But, since f is an isomorphism, $x' \subseteq x$ follows.

In the other direction, if $X \in x$, then $f(\uparrow X) \subseteq f(x')$ holds by definition, so $\uparrow X \subseteq x'$. This implies $X \in x'$; and, as X is arbitrary, $x \subseteq x'$. So $x = x'$, and $f(x) = f(x')$ as desired.

Finally, consider any finite element $\uparrow X \in |D_0|$, where $X \in D_0$. What we have to show is that $f(\uparrow X)$ is finite in $|D_1|$. Because f is an isomorphism, we can associate uniquely to every $Y \in f(\uparrow X)$ an element $y_Y \subseteq\uparrow X$ in $|D_0|$ where $f(y_Y) =\uparrow Y$. (Just apply the inverse of the function f.) Define

$$z = \bigcup\{y_Y \mid Y \in f(\uparrow X)\}.$$

Because $Y' \subseteq Y$ always implies $y_{Y'} \subseteq y_Y$ and each $y_Y \in |D_0|$, it is easy to show z is a filter and hence is in $|D_0|$ also (cf. Exercise 2.11). Because each $y_Y \subseteq\uparrow X$, then $z \subseteq\uparrow X$, too. But each $y_Y \subseteq z$, so $\uparrow Y = f(y_Y) \subseteq f(z)$ and hence $Y \in f(z)$. As this holds for all $Y \in f(\uparrow X)$, the inclusion $f(\uparrow X) \subseteq f(z)$ follows, as well as $\uparrow X \subseteq z$. Therefore, $z =\uparrow X$ and so $X \in z$. But then $X \in y_Y$ for some $Y \in f(\uparrow X)$, by definition of z. Since $\uparrow X \subseteq y_Y$, we obtain $f(\uparrow X) \subseteq\uparrow Y$, but of course the opposite inclusion is also true from the choice of Y. This means that $f(\uparrow X) =\uparrow Y$ is finite in $|D_1|$ as claimed. We can apply the same argument to the inverse function; and, thus, the finite elements of $|D_0|$ and $|D_1|$ are in a one-one inclusion-preserving correspondence under the isomorphism. □

Theorem (`theorem_2_7`). Every order isomorphism of ideal elements arises as the elementwise action of an approximable map, and principal filters are sent to principal filters.

Proof. Assemble the existence of an approximable realization and the principal-to-principal lemma. ■

4.3.15 Monotone on principals as approximable map

Approximable maps determined by their action on principal filters, and the approximable map induced by a monotone assignment of ideal elements to neighbourhoods.

Definition (`ofMono`). A monotone assignment of ideal elements to neighbourhoods induces an approximable map: X relates to Y when Y belongs to the assigned element at X.

Proof. Domain and codomain membership are immediate; master, intersection, and monotonicity follow from the corresponding properties of the assigned elements and the monotonicity hypothesis. ■

Theorem (`eq_of_toElementMap_principal`). Approximable maps that agree on all principal filters are equal.

Proof. Recover the neighbourhood relation from evaluation at principals. ■

Theorem (`toElementMap_ofMono_principal`). The elementwise action of the induced map at a principal filter recovers the assigned element.

Proof. Membership in the image comes from a smaller neighbourhood by monotonicity; conversely the neighbourhood itself witnesses the relation. ■

4.3.16 Exercise 2.8 — determined by finite elements

With reference to the proof of 2.2 show that an approximable mapping is uniquely determined by its elementwise effect on finite elements. Moreover any arbitrary monotone function on finite elements of $|D_0|$ with values in $|D_1|$ comes from an approximable $f : D_0 \to D_1$.

Theorem (`exercise_2_8`). Approximable maps that agree on all principal filters are equal, and every monotone assignment of ideal elements to neighbourhoods arises as the principal action of the induced approximable map.

Proof. Assemble uniqueness on principals with recovery of the assigned element at each principal. ■

4.3.17 Exercise 2.9 — directed union formula

Prove that if $f : D_0 \to D_1$ is an approximable mapping, then the elementwise mapping $f : |D_0| \to |D_1|$ satisfies the equation

$$f(x) = \bigcup \{ f(\uparrow X) \mid X \in x \}$$

for all $x \in |D_0|$. Conversely, show that every elementwise function satisfying this equation comes from an approximable mapping as defined in 2.2.

Theorem (`exercise_2_9`). Membership in the elementwise image is witnessed by a principal approximation: a neighbourhood belongs to $f(x)$ if and only if it belongs to $f(\uparrow X)$ for some neighbourhood X of x.

Proof. This is the membership form of the directed-union equation; it is the corresponding library fact for the elementwise action. ■

4.3.20 Indexed directed supremum of ideal elements

Directed joins of ideal elements presented by an index type, and preservation of those joins by approximable maps.

Definition (`iSupDirected`). The directed supremum of a nonempty directed family of ideal elements, presented as a function on an index type, is the directed join of the range of that function.

Theorem (`mem_iSupDirected`). A neighbourhood belongs to the indexed directed supremum if and only if it belongs to some term of the family.

Theorem (`iSupDirected_le`). The indexed directed supremum is below any common upper bound of the family.

Theorem (`le_iSupDirected`). Each term of the family is below the indexed directed supremum.

Theorem (`toElementMap_iSupDirected`). The elementwise action of an approximable map preserves indexed directed suprema.

Proof. Membership in the image of the join is membership for some term, transported by the defining formula for the elementwise action. ■

4.3.21 Exercise 2.11 — directed unions of elements

Let $(I, \leq)$ be a non-empty abstract partially ordered set; suppose it is directed in the sense that whenever $i, j \in I$, then $i \leq k$ and $j \leq k$ for some $k \in I$. Suppose that $a : I \to |D|$ is such that

$$i \leq j \text{ implies } a_i \subseteq a_j$$

for all $i, j \in I$. Prove that

$$\bigcup \{a_i \mid i \in I\}$$

is always a filter in $|D|$. (Note the ways this lemma could be used in the proof of 2.7; but be careful in defining the partially ordered set and do not confuse $\subseteq$ and $\supseteq$.) In words we could say that the domain of filters is closed under directed unions. Prove also that if $f : D \to D'$ is an approximable mapping, then for any directed union

$$f(\bigcup\{a_i \mid i \in I\}) = \bigcup\{f(a_i) \mid i \in I\};$$

that is, approximable mappings always preserve directed unions. If an elementwise function preserves directed unions, must it come from an approximable mapping? (Hint: Invoke 2.9.)

Theorem (`exercise_2_11`). Domains are closed under indexed directed unions of ideal elements (membership in the join is membership in some term), and approximable maps preserve those unions elementwise.

Proof. Assemble the membership characterization of the indexed directed supremum with preservation under the elementwise action. ■

4.3.24 Continuous maps as approximable

Continuous maps of ideal elements as approximable maps, and the converse continuity of elementwise actions.

Definition (`instNonemptyMemSubtype`). For each ideal element, the type of neighbourhoods belonging to that element is nonempty (witnessed by the master neighbourhood).

Theorem (`continuous_monotone`). A continuous map of ideal elements is monotone for the approximation order.

Proof. Preimages of opens are open, and opens are upper sets for approximation. ■

Theorem (`mem_iff_principal_of_continuous`). Under a continuous map, a neighbourhood belongs to the image of an ideal element if and only if it belongs to the image of some principal filter of a neighbourhood of that element.

Proof. One direction uses continuity at the basic open determined by the neighbourhood; the converse uses monotonicity of continuous maps. ■

Theorem (`principalFamily_directed`). The family of principal filters of neighbourhoods of a fixed ideal element is directed under approximation.

Proof. Intersect two neighbourhoods and compare principals by the principal-order characterisation. ■

Theorem (`eq_iSupDirected_principal`). Every ideal element is the indexed directed supremum of the principal filters of its neighbourhoods.

Proof. Membership on either side rearranges the directed-join formula against the filter axioms. ■

Theorem (`continuous_of_monotone_iSupDirected`). A monotone map of ideal elements that preserves indexed directed joins is continuous.

Proof. Express the point as the directed join of its principals, apply preservation of joins, and extract a basic open neighbourhood from membership in an open of the image. ■

Definition (`ofContinuous`). A continuous map of ideal elements induces an approximable map by evaluating the continuous map on principal filters.

Proof. Monotonicity of the assignment follows from continuity. ■

Theorem (`continuous_toElementMap`). The elementwise action of an approximable map is continuous.

Proof. Membership of the image in an open is witnessed by a related neighbourhood, which supplies a basic open preimage. ■

Theorem (`toElementMap_ofContinuous`). The elementwise action of the approximable map induced by a continuous map recovers that continuous map.

Proof. Compare membership via the principal-union law for continuous maps and evaluation of the induced map on principals. ■

4.3.25 Exercise 2.13 — approximable means continuous

(For topologists.) Recall Exercise 1.22 where it was shown that any domain $|D|$ is a topological space. Prove from Exercise 2.9 that the functions $f : |D_0| \to |D_1|$ determined by approximable mappings are exactly *the continuous functions between these spaces.* (Hint: To prove continuity, remark that by 2.9

$$f^{-1}[Y] = \bigcup\{[X] \mid Y \in f(\uparrow X)\};$$

hence, the inverse image of any open set is open. In the other direction, suppose that $f : |D_0| \to |D_1|$ is topologically continuous. Argue that for all $x \in |D_0|$ and all open subsets $U \subseteq |D_1|$ we have

$$f(x) \in U \text{ iff } \exists X \in x.\ f(\uparrow X) \in U.$$

This holds because an open subset of $|D_0|$ is always a union of basic open subsets of the form $[X']$ for $X \in D_0$ and because

$$x = \bigcup\{\uparrow X \mid X \in x\}$$

for all $x \in |D_0|$.)

Theorem (`exercise_2_13`). Elementwise actions of approximable maps are continuous; continuous maps of ideal elements satisfy the principal-union membership law; and every continuous map arises as the elementwise action of an approximable map.

Proof. Continuity of elementwise actions, the principal-union law for continuous maps, and recovery of a continuous map from its induced approximable map. ■

4.3.26 Neighbourhood correspondence of an order isomorphism

The neighbourhood correspondence induced by an order isomorphism of ideal elements, its preservation of intersections, and the containment characterisation of the induced approximable map.

Definition (`phi`). An order isomorphism of ideal elements determines a neighbourhood correspondence: the image of the principal filter of a neighbourhood is again a principal filter, and φ selects that neighbourhood.

Theorem (`phi_mem`). The selected neighbourhood is a neighbourhood of the codomain system.

Proof. Part of the choice data from the principal-image theorem. ■

Theorem (`phi_spec`). Applying the isomorphism to the principal filter of a neighbourhood yields the principal filter of the corresponding neighbourhood.

Proof. The remaining clause of that choice data. ■

Theorem (`phi_inter`). The correspondence preserves intersections of consistent neighbourhoods.

Proof. Compare principals via monotonicity of the isomorphism and its inverse; the least-upper-bound property of the intersection principal yields both inclusions. ■

Theorem (`rel_ofIso_iff`). The approximable map induced by the isomorphism relates X to Y if and only if Y is a neighbourhood containing the corresponding neighbourhood of X.

Proof. Rewrite membership in the image principal via the correspondence specification. ■

4.3.27 Exercise 2.14 — isomorphisms of neighbourhoods

Let $f : |D_0| \to |D_1|$ be an isomorphism between domains. Let $\varphi : D_0 \to D_1$ be the one-one correspondence between neighbourhoods provided by Theorem 2.7 where

$$f(\uparrow X) = \uparrow \varphi(X)$$

for all $X \in D_0$. Show that the approximable mapping determined by f is just the relationship $\varphi(X) \subseteq Y$. In addition prove that if $X, X' \in D_0$ are consistent, then

$$\varphi(X \cap X') = \varphi(X) \cap \varphi(X').$$

Remark that the isomorphisms between domains correspond exactly to the isomorphisms between neighbourhood systems (in the sense of one-one inclusion preserving correspondences).

Theorem (`example_214`). The neighbourhood correspondence of an order isomorphism preserves intersections of consistent neighbourhoods, and the induced approximable map relates neighbourhoods exactly by containment after that correspondence.

Proof. Intersection preservation and the containment characterisation of the induced relation. ■

4.3.28 One-token Sierpiński neighbourhood system

The one-token Sierpiński neighbourhood system, and the correspondence between its approximable maps and open subsets of a domain.

Definition (`memO`). A subset of the one-token set is a Sierpiński neighbourhood when it is the whole set or empty.

Theorem (`nestedOrDisjoint_O`). Any two Sierpiński neighbourhoods are nested or disjoint.

Proof. Case analysis on the two alternatives. ■

Theorem (`subMaster_O`). Every Sierpiński neighbourhood is contained in the universe.

Proof. Immediate. ■

Definition (`O`). The one-token Sierpiński neighbourhood system has master the universe and neighbourhoods the universe and the empty set.

Theorem (`O_mem`). Membership in the Sierpiński system is the Sierpiński neighbourhood predicate.

Proof. By definition. ■

Theorem (`O_master`). The master of the Sierpiński system is the universe.

Proof. By definition. ■

Theorem (`O_mem_empty`). The empty set is a Sierpiński neighbourhood.

Proof. One of the two alternatives in the neighbourhood predicate. ■

Theorem (`O_inter_mem`). The intersection of two Sierpiński neighbourhoods is a Sierpiński neighbourhood.

Proof. Intersecting with the universe leaves the other factor; intersecting with empty yields empty. ■

Definition (`botElt`). The bottom ideal element of the Sierpiński system is the bottom filter.

Theorem (`mem_botElt`). A neighbourhood belongs to the bottom element if and only if it is the universe.

Proof. Specialise the characterisation of the bottom filter to the Sierpiński master. ■

Definition (`topElt`). The top ideal element of the Sierpiński system is the principal filter of the empty neighbourhood.

Definition (`mapToOpen`). An approximable map into the Sierpiński system determines the set of ideal elements sent to top.

Theorem (`mem_empty_iff_eq_top`). An ideal element of the Sierpiński system contains the empty neighbourhood if and only if it is top.

Proof. The empty set is minimal among neighbourhoods, so membership characterises the corresponding principal; the converse is immediate. ■

Theorem (`element_eq_bot_or_top`). Every ideal element of the Sierpiński system is bottom or top.

Proof. If it contains empty it is top; otherwise its neighbourhoods are forced to be those of bottom. ■

Theorem (`O_ext`). Ideal elements of the Sierpiński system that agree on membership of empty are equal.

Proof. Both are bottom or both are top by the preceding dichotomy. ■

Theorem (`isOpen_mapToOpen`). The set of points sent to top by an approximable map into the Sierpiński system is open.

Proof. It is the preimage of the basic open of the empty neighbourhood under the continuous element-wise action. ■

Theorem (`univ_ne_empty`). The universe of the one-token set is nonempty.

Proof. It contains the unique token. ■

Definition (`openToMap`). An open set of ideal elements induces an approximable map into the Sierpiński system: a neighbourhood relates to a Sierpiński neighbourhood when the latter is empty only if the principal of the former lies in the open.

Proof. Domain, codomain, and master are immediate; intersection and monotonicity use the filter and upper-set properties of opens. ■

Theorem (`toElementMap_openToMap_principal_mem_empty`). Under the induced map, the image of a principal contains empty if and only if that principal lies in the open.

Proof. Unpack the defining relation at the principal. ■

Theorem (`mem_mapToOpen_openToMap`). Points belonging to the open recovered from the map induced by an open are exactly the points of that open.

Proof. One direction uses the principal-membership law and that opens are upper sets; the converse extracts a basic open neighbourhood from the open-filter property. ■

Theorem (`openToMap_mapToOpen`). The map induced by the open recovered from an approximable map into the Sierpiński system recovers that map.

Proof. Compare on principals via the empty-membership characterisation and uniqueness of Sierpiński elements by empty-membership. ■

4.3.29 Exercise 2.15 — opens classified by maps

(For topologists.) Consider the one-token system with

$$\mathcal{O} = \{\{0\}, \emptyset\}.$$

We can regard $|\mathcal{O}|$ as having just two finite elements $\bot$ (bottom) and $\top$ (top), where $\bot \sqsubseteq \top$. For any system D, show that the open subsets U of $|D|$ are in a one-one correspondence with the approximable mappings $f : D \to \mathcal{O}$, where the correspondence is given by the equation

$$U = \{x \in |D| \mid f(x) = \top\}.$$

What are the open subsets of $|\mathcal{O}|$? of $|\mathbb{T}|$? of $|\mathbb{B}|$?

Theorem (`example_215`). Opens of a domain are recovered as the points sent to top by the approximable map they induce into the Sierpiński system, and every approximable map into that system arises from the open it classifies.

Proof. Round-trip membership for the open recovered from an induced map, and recovery of a map from the open it classifies. ■

4.3.30 Prefixing map and parity equations

The approximable map that prefixes by a fixed string, and uniqueness of the parity map among solutions of its three equations.

Definition (`SatisfiesParityEquations`). An approximable map from binary trees to the two-token system satisfies the parity equations when it sends a one-prefixed element to true, a zero-one-prefixed element to false, and a zero-zero-prefixed element to the image of the unprefixed element.

Definition (`sigmaMap`). Prefixing neighbourhoods by a fixed string determines an approximable endomap of the binary-tree system: X relates to Y when the prefix of X is contained in Y.

Proof. Domain and codomain membership are immediate; master uses the two masters; intersection and monotonicity follow from the corresponding properties of prefixed neighbourhoods. ■

Theorem (`key`). A map satisfying the parity equations agrees on bottoms of cones with the scan-value of the parity map.

Proof. Induction on the string, using the three equations and comparison of bottoms under prefixing. ■

Theorem (`eq_parityMap_of_satisfies`). Any approximable map satisfying the parity equations equals the parity map.

Proof. Compare neighbourhood relations via evaluation at principal filters and the preceding key lemma. ■

Theorem (`parityMap_satisfies`). The parity map satisfies the parity equations.

Proof. Unpack the elementwise formula for the parity map on prefixed elements against the scan-append rules. ■

Theorem (`toElementMap_sigmaMap`). The elementwise action of the prefixing map is prefixing of ideal elements.

Proof. Membership rearranges between the defining relation and the definition of prefixed elements. ■

4.3.31 Exercise 2.16 — prefixing is approximable

In the discussion of $\mathbb{B}$ in Chapter 1 we defined a mapping $x \mapsto \sigma x$ for any given $\sigma \in \Sigma^*$. Is this (elementwise) mapping approximable? Show in addition that the mapping $f : \mathbb{B} \to \mathbb{T}$ of 2.3 is uniquely determined among approximable mappings by the equations:

$$f(1x) = \text{true},$$
$$f(01x) = \text{false, and}$$
$$f(00x) = f(x).$$

Theorem (`example_216`). The parity map is the unique approximable map satisfying the three parity equations, and prefixing by a fixed string is the elementwise action of an approximable endomap.

Proof. Uniqueness among solutions of the parity equations, and recovery of prefixed ideal elements from the prefixing map. ■

4.3.32 Uniqueness of the erase-ones map

Uniqueness of the erase-ones approximable map among solutions of the run equations, and verification that the erase-ones map satisfies those equations.

Theorem (`eq_runMap_of_satisfies`). Any approximable endomap of the binary-tree system that satisfies the run equations equals the erase-ones map.

Proof. Compare neighbourhood relations via evaluation at principal filters and the key lemma relating solutions of the equations to the erase-ones string map. ■

Theorem (`runMap_toElementMap_mem`). Membership in the elementwise image of the erase-ones map is witnessed by a cone whose erased output is contained in the neighbourhood.

Proof. Unpack the defining relation on cones. ■

Theorem (`runMap_toElementMap_sigmaElt`). Membership in the image of a prefixed ideal element under the erase-ones map is membership after erasing ones from the concatenated string.

Proof. Transport the cone formula through prefixing of neighbourhoods and monotonicity of the erase-ones string map. ■

Theorem (`sigmaElt_runMap_toElementMap`). Membership after prefixing the erase-ones image is membership for a cone whose output is prefixed by the fixed string.

Proof. Reassociate prefixing of neighbourhoods with the elementwise membership formula. ■

Theorem (`runMap_satisfies`). The erase-ones map satisfies the run equations.

Proof. Compare the prefixed membership formulae against the string identities for leading zero, two ones, one-zero, and a lone one on bottom. ■

4.3.33 Exercise 2.17 — erase-ones map

Establish in detail that the mapping $g : \mathbb{B} \to \mathbb{B}$ of Exercise 2.4 is approximable. Is it uniquely determined by these equations:

$$g(0x) = 0g(x),$$
$$g(11x) = g(1x),$$

$$g(10x) = 0x,$$
$$g(1) = \bot$$

or are some missing?

Theorem (`exercise_2_17`). The erase-ones map is the unique approximable endomap of the binary-tree system satisfying the run equations, and those equations hold of the erase-ones map.

Proof. Uniqueness among solutions of the run equations, and verification that the erase-ones map satisfies them. Approximability is the construction of the erase-ones map. ■

Exercise_2_17.lean

```
module

```

4.3.34 Insert-zero map and left inverse

The insert-zero approximable map on binary trees, its left inverse that drops alternate bits, and the failure of surjectivity and injectivity for those maps.

Definition (`hOut`). Insert a zero after each bit of a string.

Theorem (`hOut_nil`). Inserting zeros into the empty string yields empty.

Theorem (`hOut_cons`). Inserting zeros after a leading bit yields that bit, a zero, and the recursively expanded tail.

Theorem (`hOut_append`). Inserting zeros is monotone for string prefix.

Proof. Induction on the prefix. ■

Theorem (`hOut_mono`). Prefix-comparable strings remain so after inserting zeros.

Proof. Unpack the prefix witness and apply the append form. ■

Definition (`kOut`). Drop every other bit of a string, truncating a lone leftover bit to empty.

Theorem (`kOut_nil`). Dropping alternate bits of empty yields empty.

Theorem (`kOut_single`). A singleton string drops to empty.

Theorem (`kOut_cons`). Dropping alternate bits after two leading bits keeps the first and continues on the remainder.

Definition (`hMap`). The approximable endomap of the binary-tree system that relates a cone on σ to neighbourhoods containing the cone on the zero-inserted string.

Proof. Master, intersection, and monotonicity follow from injectivity of cones and monotonicity of the insert-zero string map. ■

Theorem (`kOut_append`). Dropping alternate bits is monotone for string prefix.

Proof. Induction on the shape of the prefix. ■

Theorem (`kOut_mono`). Prefix-comparable strings remain so after dropping alternate bits.

Proof. Unpack the prefix witness and apply the append form. ■

Definition (`kMap`). The approximable endomap that relates a cone on σ to neighbourhoods containing the cone on the alternate-bit drop of σ.

Proof. As for the insert-zero map, using monotonicity of the drop string map. ■

Theorem (`kOut_hOut`). Dropping alternate bits after inserting zeros recovers the original string.

Proof. Induction on the string. ■

Theorem (`kMap_comp_hMap`). Composition of the drop map after the insert-zero map is the identity approximable map.

Proof. Compare neighbourhood relations using the string identity and monotonicity of the drop map. ■

Theorem (`toElementMap_hMap_cone`). The elementwise action of the insert-zero map on a principal cone is the principal cone of the zero-inserted string.

Proof. Unpack the defining relation at the cone. ■

Theorem (`toElementMap_kMap_cone`). The elementwise action of the drop map on a principal cone is the principal cone of the alternate-bit drop.

Proof. Unpack the defining relation at the cone. ■

Theorem (`hMap_not_surjective`). The elementwise action of the insert-zero map is not surjective.

Proof. A left inverse would force an impossible string identity on a two-bit cone in the image. ■

Theorem (`kMap_not_injective`). The elementwise action of the drop map is not injective.

Proof. Distinct one-bit principals collapse under the drop map. ■

4.3.35 Exercise 2.18 — doubling binary digits

What is the meaning in words of the approximable mapping $h : \mathbb{B} \to \mathbb{B}$, where

$$h(0x) = 00h(x), \text{ and}$$
$$h(1x) = 10h(x),$$

for all elements $x \in |\mathbb{B}|$? Is h an isomorphism? Does there exist a map $k : \mathbb{B} \to \mathbb{B}$ where

$$k \circ h = I_{\mathbb{B}},$$

and is k one-one?

Theorem (`example_218`). The insert-zero map is not surjective on ideal elements, admits a left inverse under composition of approximable maps, and that left inverse is not injective.

Proof. Failure of surjectivity, the left-inverse identity, and failure of injectivity. ■

`Exercise_2_18.lean`

4.3.36 Approximable maps of two arguments

Approximable mappings of two arguments as ternary neighbourhood relations, their elementwise action on pairs of ideal elements, and the correspondence with approximable maps out of a product.

Definition (`ApproximableMap2`). An approximable mapping of two arguments is a ternary relation on neighbourhoods that relates only neighbourhoods of the respective systems, relates the three masters, is closed under intersection in the third argument, and is monotone when the first two neighbourhoods shrink and the third expands.

Definition (`toElementMap2`). The elementwise action of a binary approximable map on a pair of ideal elements collects those neighbourhoods related to some neighbourhoods of each argument.

Proof. Codomain membership, master, intersection, and upward closure follow from the corresponding axioms of the ternary relation. ■

Theorem (`mem_toElementMap2`). Membership in the elementwise image is existence of witnessing neighbourhoods of each argument related to the given neighbourhood.

Proof. By definition. ■

Theorem (`rel2_iff_mem_principal`). The ternary relation holds of neighbourhoods if and only if the corresponding neighbourhood belongs to the elementwise image of their principal filters.

Proof. One direction evaluates at the principals; the converse uses monotonicity to shrink to the given neighbourhoods. ■

Theorem (`toElementMap2_mono`). The elementwise action is monotone in each argument for the approximation order.

Proof. Membership witnesses transport along the inequalities. ■

Theorem (`ApproximableMap2.ext`). Ternary relations that agree on all triples of neighbourhoods determine equal binary approximable maps.

Proof. Unpack the structure and compare the relation fields. ■

Definition (`ofMap2`). A binary approximable map determines an approximable map out of the product by relating a product neighbourhood to a codomain neighbourhood when the ternary relation holds of the two untagged factors.

Proof. Approximable-map axioms follow from the ternary axioms and the product neighbourhood laws. ■

Definition (`toMap2`). An approximable map out of a product determines a binary approximable map by evaluating at products of neighbourhoods.

Proof. The ternary axioms follow from the unary ones and nesting of product neighbourhoods. ■

Theorem (`ofMap2_toMap2`). Converting a product map to a binary map and back recovers the original.

Proof. Compare relations using recovery of a product neighbourhood from its untaggings. ■

Theorem (`toMap2_ofMap2`). Converting a binary map to a product map and back recovers the original.

Proof. Compare ternary relations using untagging of a product of neighbourhoods. ■

Definition (`map2Equiv`). Approximable maps out of a product are equivalent to binary approximable maps via the two conversions.

Proof. The round-trip identities. ■

Theorem (`toElementMap2_toMap2`). The elementwise action of the binary form of a product map at a pair of ideal elements equals the unary elementwise action at their pairing.

Proof. Compare membership by unpacking product neighbourhoods into factors. ■

4.3.37 Exercise 2.19 — maps of two arguments

Generalize Definition 2.1 in an appropriate way in order to define the concept of *an approximable mapping*

$$f : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2$$

of two variables. (Hint: f can be taken to be a certain kind of ternary relation

$$f \subseteq \mathcal{D}_0 \times \mathcal{D}_1 \times \mathcal{D}_2,$$

where we can write

$$X, Y \; f \; Z$$

for the relationship among neighbourhoods.) What is the corresponding version of Proposition 2.2 for functions of two variables?

Theorem (`exercise_2_19`). Membership in the elementwise image of a binary approximable map is witnessed by related neighbourhoods of each argument; the ternary relation is recovered by evaluating at principals; and the elementwise action is monotone in each argument.

Proof. The membership characterisation, the principal-recovery law, and monotonicity of the elementwise action. The ternary relation itself is the two-variable generalisation of approximable maps. ■

4.3.38 Powerset neighbourhood system

The powerset neighbourhood system on the naturals, its identification with arbitrary subsets, and approximable union, intersection, successor, and predecessor maps.

Definition (`powerSet`). The powerset neighbourhood system on the naturals takes as neighbourhoods those sets whose complements are finite, with master the universe.

Proof. The empty complement is finite; intersecting neighbourhoods unions their finite complements; every neighbourhood sits in the universe. ■

Theorem (`mem_powerSet`). A set is a powerset neighbourhood if and only if its complement is finite.

Proof. By definition. ■

Theorem (`powerSet_master`). The master is the universe.

Proof. By definition. ■

Theorem (`mem_compl_singleton`). The complement of a singleton is a powerset neighbourhood.

Proof. Its complement is a singleton, hence finite. ■

Theorem (`powerSet_inter_mem`). The intersection of two powerset neighbourhoods is a powerset neighbourhood.

Proof. Complements of intersections are unions of finite sets. ■

Definition (`toSet`). The set of naturals corresponding to an ideal element consists of those n for which the complement of $\{n\}$ belongs to the element.

Theorem (`mem_toSet`). Membership of n in the corresponding set is membership of the complement of $\{n\}$ in the ideal element.

Proof. By definition. ■

Theorem (`mem_compl_of_finite`). If a finite set of naturals each have their singleton-complements in an ideal element, then the complement of that finite set belongs to the element.

Proof. Induction on the finite set, using intersection of filters. ■

Definition (`ofSet`). An arbitrary subset of the naturals determines an ideal element consisting of those neighbourhoods whose complements are contained in the subset.

Proof. Master, intersection, and upward closure follow from the corresponding set operations on complements. ■

Theorem (`ofSet_mono`). Larger subsets determine larger ideal elements in the approximation order.

Proof. Containment of complements is preserved by enlarging the ambient set. ■

Theorem (`ofSet_toSet`). Passing from an ideal element to its set and back recovers the element.

Proof. Membership of a neighbourhood rearranges via the finite-complement characterisation against the corresponding set. ■

Definition (`predSet`). The predecessor of a set of naturals consists of those n with $n + 1$ in the set.

Theorem (`mem_predSet`). Membership in the predecessor set is membership of the successor in the original set.

Proof. By definition. ■

Definition (`interMap2`). Intersection of ideal elements is the binary approximable map relating neighbourhoods when their union is contained in the third.

Proof. Domain, codomain, master, intersection, and monotonicity follow from the powerset neighbourhood axioms and union of sets. ■

Theorem (`predSet_mono`). Predecessor is monotone for set inclusion.

Proof. Immediate. ■

Definition (`predMap`). The predecessor transformation is the approximable map relating neighbourhoods when the complement of the codomain neighbourhood is contained in the predecessor of the complement of the domain neighbourhood.

Proof. As for other complement-based maps on the powerset system. ■

Definition (`succSet`). The successor of a set of naturals is the image under $n \mapsto n + 1$.

Theorem (`succSet_mono`). Successor is monotone for set inclusion.

Proof. Images preserve inclusions. ■

Definition (`succMap`). The successor transformation is the approximable map relating neighbourhoods when the complement of the codomain neighbourhood is contained in the successor of the complement of the domain neighbourhood.

Proof. As for the predecessor map. ■

Theorem (`toSet_ofSet`). Passing from a set to an ideal element and back recovers the set.

Proof. Membership of a natural rearranges against singleton-complements. ■

Definition (`equivSetNat`). Ideal elements of the powerset system are order-isomorphic to arbitrary subsets of the naturals via the to-set / of-set correspondence.

Proof. The two round-trips and the order correspondence follow from the preceding lemmas. ■

Definition (`unionMap`). Union of ideal elements is the binary approximable map relating neighbourhoods when their intersection is contained in the third.

Proof. Dual to the intersection map. ■

Theorem (`toSet_interMap2`). Under the set identification, the elementwise action of the intersection map is intersection of sets.

Proof. Compare membership of a natural via singleton-complements and the defining relation. ■

Theorem (`toSet_predMap`). Under the set identification, the elementwise action of the predecessor map is the predecessor of sets.

Proof. Compare membership via singleton-complements and the defining relation. ■

Theorem (`toSet_succMap`). Under the set identification, the elementwise action of the successor map is the successor of sets.

Proof. Compare membership via singleton-complements and the defining relation. ■

Theorem (`toSet_unionMap`). Under the set identification, the elementwise action of the union map is union of sets.

Proof. Compare membership via singleton-complements and the defining relation. ■

4.3.39 Exercise 2.20 — powerset of the integers

Discuss again the example of Exercise 1.15 where the domain turns out to be the powerset (set of all subsets) of $\mathbf{N}$. Show how the finite elements can be taken to be the finite subsets of $\mathbf{N}$ and can be identified with the tokens of a suitable neighbourhood system $\mathcal{P}$. (Hint: Define $\uparrow F$ for finite sets $F \subseteq \mathbf{N}$.) Show that both union and intersection ($x \cup y$ and $x \cap y$) are functions on $|\mathcal{P}|$ that are approximable in the sense of Exercise 2.19. (The elements of $|\mathcal{P}|$ are being identified with arbitrary sets $x \subseteq \mathbf{N}$.) Show also that the following transformations are approximable:

$$x + 1 = \{n + 1 \mid n \in x\}, \text{ and}$$
$$x - 1 = \{n \mid n + 1 \in x\}.$$

Theorem (`example_220`). Under the identification of ideal elements with subsets of the naturals, the elementwise images of the binary union and intersection maps recover set-theoretic union and intersection, and the elementwise images of the successor and predecessor maps recover the corresponding set transformations.

Proof. The four recovery laws for the powerset maps. ■

4.3.40 Finite and infinite sequence neighbourhood system

The neighbourhood system of finite and infinite binary sequences, with cones and terminator singletons as tokens, the empty total sequence above bottom, and left-biased approximable juxtaposition.

Theorem (`cone_not_subset_singleton`). No cone is contained in a singleton.

Proof. A cone contains both a string and a proper extension, which cannot both lie in one singleton. ■

Theorem (`cone_ne_singleton`). No cone equals a singleton.

Proof. Equality would force the cone into the singleton. ■

Theorem (`cone_singleton_nd`). A cone and a singleton are nested or disjoint.

Proof. If the cone tip prefixes the singleton string then the singleton sits in the cone; otherwise their intersection is empty. ■

Definition (`memC`). A set of strings is a neighbourhood of the enlarged system when it is a cone or a singleton.

Theorem (`singleton_cone_nd`). A singleton and a cone are nested or disjoint.

Proof. Dual to the cone–singleton case via the prefix relation. ■

Theorem (`singleton_singleton_nd`). Two singletons are nested or disjoint.

Proof. Equal strings give nesting; unequal strings give empty intersection. ■

Theorem (`nestedOrDisjoint_C`). Any two neighbourhoods of the enlarged system are nested or disjoint.

Proof. Case analysis on cones versus singletons, using the four nested-or-disjoint lemmas. ■

Definition (`C`). The enlarged neighbourhood system on binary strings has master the universe and neighbourhoods the cones together with the terminator singletons.

Proof. Nested-or-disjoint construction with the empty-cone master. ■

Theorem (`C_mem`). Membership in the enlarged system is the cone-or-singleton predicate.

Proof. By definition. ■

Theorem (`C_master`). The master of the enlarged system is the universe.

Proof. By definition. ■

Theorem (`memC_cone`). Every cone is a neighbourhood of the enlarged system.

Proof. One of the two alternatives in the neighbourhood predicate. ■

Theorem (`memC_singleton`). Every singleton is a neighbourhood of the enlarged system.

Proof. The other alternative in the neighbourhood predicate. ■

Theorem (`prepend_mono`). Prepending a fixed string is monotone for set inclusion.

Proof. Immediate from the definition of prepend. ■

Theorem (`prepend_singleton`). Prepending a string to a singleton yields the singleton of the concatenation.

Proof. Unpack membership in the prepended set. ■

Theorem (`memC_prepend`). Prepending a string to a neighbourhood of the enlarged system yields a neighbourhood.

Proof. Prepending to a cone yields a cone; prepending to a singleton yields a singleton. ■

Theorem (`prepend_subset_cone`). The prepend of any set under a string sits inside that string's cone.

Proof. Concatenation witnesses the prefix relation. ■

Definition (`singletonElt`). The ideal element associated to a finite total sequence is the principal filter of its terminator singleton.

Definition (`Lambda`). The empty total sequence is the singleton element of the empty string.

Theorem (`subset_singleton_eq`). A neighbourhood contained in a singleton equals that singleton.

Proof. Cones never sit in singletons; a singleton contained in another forces equality of tips. ■

Definition (`juxtapose`). Juxtaposition is the binary approximable map relating neighbourhoods when either the left is a cone contained in the result, or the left is a singleton whose prepend of the right neighbourhood sits in the result.

Proof. Domain, codomain, master, intersection, and monotonicity follow from the neighbourhood axioms, injectivity of cones, and the prepend lemmas. ■

Theorem (`bot_lt_Lambda`). Bottom is strictly below the empty total sequence.

Proof. Bottom's only neighbourhood is the master, which cannot equal the empty singleton. ■

Theorem (`isTotal_singletonElt`). Every finite terminator element is total.

Proof. Any neighbourhood of a larger element meeting the terminator singleton must recover that singleton by the subset-singleton law. ■

Theorem (`juxtapose_cone`). Juxtaposing a cone principal on the left with any right argument recovers that cone principal.

Proof. Unpack the defining relation: the cone branch forces containment in the result, and the singleton branch is impossible for a cone left argument. ■

Theorem (`juxtapose_singleton_mem`). Membership in the juxtaposition of a terminator element with a right argument is witnessed by a neighbourhood of the right whose prepend under the terminator tip sits in the result.

Proof. Compare the defining relation against the singleton left argument. ■

4.3.41 Exercise 2.21 — finite and infinite sequences

The system $\mathcal{B}$ of 2.3 has as its total elements only the infinite sequences. Modify the construction of $\mathcal{B}$ to another neighbourhood system $\mathcal{C}$ which has *both* the finite and infinite sequences as total elements. (Hint: $\mathcal{B} \subseteq \mathcal{C}$.) Show that there is an approximable map xy on elements naturally extending ordinary juxtaposition of sequences. (Hint: Write 01001 for a *total* finite sequence and $01001\,\bot$ for the corresponding finite partial element. Remember to distinguish between Λ (the total empty sequence) and $\bot$ (the undefined sequence). The definition should work out so that if x is an infinite sequence (hence, total), then $xy = x$ for all y. What will xy equal if x is not total? In other words, the construction possesses a rather strong left-to-right bias.)

Theorem (`example_221`). Bottom is strictly below the empty total sequence; every finite terminator element is total; juxtaposition of a cone principal on the left recovers that principal; and membership in the juxtaposition of a terminator element is witnessed by prepending a neighbourhood of the right argument.

Proof. Strictness of bottom below the empty total, totality of terminators, left-bias on cones, and the prepend membership law. ■

4.3.42 Token neighbourhood system of a closed family

The token neighbourhood system of a family closed under nonempty intersections (and, for the representation, directed unions), with finite tokens, closure, and the order isomorphism between ideal elements and members of the family.

Definition (`Cl`). The closure of a set of tokens is the intersection of all members of the family that contain it.

Theorem (`Cl_mem`). If a set is contained in some member of an intersection-closed family, then its closure belongs to the family.

Proof. The family of containing members is nonempty and contained in the ambient family, so the intersection axiom applies. ■

Theorem (`Cl_subset`). The closure of a set contained in a family member is contained in that member.

Proof. The member belongs to the intersecting family defining the closure. ■

Definition (`IsTok`). A set is a token for the family when it is finite and contained in some member of the family.

Definition (`Tok`). Tokens are the finite sets contained in members of the family, packaged as a subtype.

Definition (`nbhd`). The basic neighbourhood of a set of tokens consists of those tokens whose closures contain the set.

Theorem (`mem_nbhd`). Membership in a basic neighbourhood is containment of the generating set in the closure of the token.

Proof. By definition. ■

Definition (`botTok`). The empty token is the empty set, which is finite and contained in any nonempty family's chosen member.

Theorem (`nbhd_empty`). The basic neighbourhood of the empty set is the universe of tokens.

Proof. Every closure contains the empty set. ■

Theorem (`subset_Cl`). Every set is contained in its closure.

Proof. Each intersecting member contains the set by construction. ■

Theorem (`nbhd_subset_iff`). Basic neighbourhoods nest exactly when the larger generator sits in the closure of the smaller token.

Proof. One direction evaluates at the token itself; the other uses monotonicity of closure under containment in a family member. ■

Definition (`reprSystem`). The token neighbourhood system has as neighbourhoods the basic neighbourhoods of tokens, with master the universe of tokens.

Proof. The empty token witnesses a nonempty master; intersecting basic neighbourhoods is the basic neighbourhood of the union of tokens, using closure under nonempty intersections. ■

Theorem (`mem_reprSystem`). A set of tokens is a neighbourhood if and only if it is a basic neighbourhood of some token.

Proof. By definition. ■

Theorem (`reprSystem_master`). The master of the token neighbourhood system is the universe of tokens.

Proof. By definition. ■

Theorem (`directed_step`). Two basic neighbourhoods of an ideal element admit a common refinement whose closures dominate both closures.

Proof. Their intersection is again a basic neighbourhood, and evaluating at the refining token yields the two containments. ■

Definition (`famC`). The family associated to an ideal element consists of the closures of tokens belonging to that element.

Theorem (`mem_nbhd_bot`). Every ideal element contains the basic neighbourhood of the empty token.

Proof. That neighbourhood is the master. ■

Definition (`ofC`). A member of the ambient family determines the ideal element of neighbourhoods containing a basic neighbourhood of some token inside the member.

Proof. Master, intersection, and upward closure follow from the corresponding token and neighbourhood operations. ■

Definition (`toC`). An ideal element determines the union of the closures of its tokens.

Theorem (`mem_toC`). A point belongs to the set associated to an ideal element if and only if it lies in the closure of some token of that element.

Proof. Unpack the union. ■

Theorem (`exists_tok_of_finite_subset`). Every finite subset of the set associated to an ideal element sits in the closure of some token of that element.

Proof. Induction on the finite set, joining tokens via the directed-step lemma. ■

Theorem (`mem_nbhd_iff`). An ideal element contains the basic neighbourhood of a token if and only if that token sits in the associated set.

Proof. One direction uses containment in the closure; the converse extracts a refining token from the finite-subset lemma and applies neighbourhood monotonicity. ■

Theorem (`toC_mem`). Under directed-union closure of the ambient family, the set associated to an ideal element belongs to the family.

Proof. The family of closures of tokens of the element is nonempty and directed under inclusion, so the directed-union axiom applies. ■

Theorem (`ofC_toC`). Passing from an ideal element to its associated set and back recovers the element.

Proof. Compare neighbourhood membership via the basic-neighbourhood characterisation against the associated set. ■

Theorem (`toC_ofC`). Passing from a family member to an ideal element and back recovers the member.

Proof. One inclusion uses containment of tokens in the member; the other uses singleton tokens. ■

Definition (`reprIso`). Ideal elements of the token neighbourhood system are order-isomorphic to members of the ambient family via the to-set / of-set correspondence.

Proof. The two round-trips and the order correspondence follow from the preceding lemmas. ■

4.3.43 Exercise 2.22 — domains from closure properties

(For set theorists). We have remarked in Exercise 1.18 and in Exercise 2.11 that any domain $|D|$, as a family of sets (in fact, a family of subsets of the set D itself), is closed under the intersection of an arbitrary non-empty sub family and under the union of any directed sub family. For those familiar with the subject matter, the example of the (proper) ideals of a commutative ring (with unit) is also seen to be such a family. What is the abstract situation? Let $\mathbf{C}$ be *any* family of sets with these closure properties. It is to be shown that $\mathbf{C}$ is inclusion-isomorphic to a domain. (Hint: Let Δ be the set of finite sets included in sets in $\mathbf{C}$. For $F \in \Delta$, define its "closure" by the equation:

$$\overline{F} = \bigcap \{X \in \mathbf{C} \mid F \subseteq X\}.$$

Every $\overline{F} \in \mathbf{C}$, and these will prove to be the "finite" elements of $\mathbf{C}$. The neighbourhood system $\mathcal{D}$ over Δ can be taken to be the sets of the form

$$C(F) = \{G \in \Delta \mid F \subseteq \overline{G}\}$$

for $F \in \Delta$. Notice that for all $X \in \mathbf{C}$

$$X = \bigcup \{\overline{F} \mid F \subseteq X \text{ and } F \in \Delta\}.$$

)

Check that approximable functions on these families are just those preserving directed unions.

Theorem (`example_222`). A nonempty family of sets closed under nonempty intersections and directed unions is inclusion-order-isomorphic to the domain of ideal elements of its token neighbourhood system.

Proof. The representation order isomorphism. ■

4.4.1 Introduction

LECTURE III

DOMAIN CONSTRUCTS

Having now seen a number of domains presented through their neighbourhood systems, we need next to introduce general constructs for forming new domains from old. There are an unlimited number of such constructs (technically called *functors*), but we have time only to single out a few of the more important ones. Outstanding among all of them is the notion of product of systems, which in our chosen category has all the expected properties. For the time being in order to simplify notation we assume of the underlying sets Δ_0 and Δ_1 of systems $\mathcal{D}_0$ and $\mathcal{D}_1$ that they are disjoint. There is no loss of generality as $\mathcal{D}_1$ can always be replaced by an isomorphic system disjoint from $\mathcal{D}_0$ in the required sense.

4.4.2 Definition 3.1 — product of systems

DEFINITION 3.1. Let neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$ be given over disjoint sets Δ_0 and Δ_1. The *product system* over $\Delta_0 \cup \Delta_1$ is defined by:

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{X \cup Y \mid X \in \mathcal{D}_0 \text{ and } Y \in \mathcal{D}_1\}.$$

For elements $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$ we also define:

$$\langle x, y \rangle = \{X \cup Y \mid X \in x \text{ and } Y \in y\}.$$

□

Definition (`prodNbhd`). The product of two sets of tokens is the disjoint union of their tagged copies in the sum type.

Theorem (`prodNbhd.mem_inl`). A left-tagged token belongs to a product neighbourhood if and only if the untagged token belongs to the left factor.

Proof. Unpack the image-union definition. ■

Theorem (`prodNbhd.mem_inr`). A right-tagged token belongs to a product neighbourhood if and only if the untagged token belongs to the right factor.

Proof. Unpack the image-union definition. ■

Theorem (`prodNbhd.inl_preimage`). The left untagging of a product neighbourhood recovers the left factor.

Proof. By the left-membership characterisation. ■

Theorem (`prodNbhd.inr_preimage`). The right untagging of a product neighbourhood recovers the right factor.

Proof. By the right-membership characterisation. ■

Theorem (`prodNbhd.injective`). Equal product neighbourhoods have equal factors.

Proof. Apply left and right untagging. ■

Theorem (`prodNbhd.inter`). Intersection of product neighbourhoods is the product of the intersections of the factors.

Proof. Case analysis on left versus right tags. ■

Theorem (`prodNbhd.subset_iff`). Product neighbourhoods nest if and only if both factors nest.

Proof. One direction evaluates at tagged tokens; the other uses monotonicity of the images. ■

Definition (`prod`). The product of two neighbourhood systems has as neighbourhoods the products of neighbourhoods from each factor, with master the product of the masters.

Proof. Master nonempty and membership follow from the left factor; intersection and containment in the master use the product intersection and nesting laws. ■

Theorem (`prod_mem_iff`). A set is a product neighbourhood if and only if it is the product of neighbourhoods from each factor.

Proof. By definition. ■

Theorem (`prod_master`). The master of a product system is the product of the masters.

Proof. By definition. ■

Theorem (`prod_mem_prodNbhd`). The product of two neighbourhoods is a neighbourhood of the product system.

Proof. Immediate from the membership characterisation. ■

Theorem (`prod_mem_prodNbhd_iff`). A product of sets is a product neighbourhood if and only if both factors are neighbourhoods.

Proof. Injectivity of the product of sets recovers the factors from any witnessing decomposition. ■

Theorem (`prodNbhd.preimage`). Every neighbourhood of a product system equals the product of its left and right untaggings.

Proof. Unpack the witnessing factors and apply the untagging identities. ■

Definition (`NeighborhoodSystem.Element.fst`). The first projection of a product ideal element consists of those left neighbourhoods whose product with the right master belongs to the element.

Proof. Filter axioms follow from intersection and nesting of product neighbourhoods. ■

Theorem (`mem_fst`). Membership in the first projection is neighbourhood membership of the left factor together with membership of its product with the right master.

Proof. By definition. ■

Definition (`NeighborhoodSystem.Element.snd`). The second projection of a product ideal element consists of those right neighbourhoods whose product with the left master belongs to the element.

Proof. Dual to the first projection. ■

Theorem (`mem_snd`). Membership in the second projection is neighbourhood membership of the right factor together with membership of its product with the left master.

Proof. By definition. ■

Definition (`pair`). The pairing of two ideal elements consists of those product neighbourhoods whose factors belong to the respective elements.

Proof. Filter axioms follow from the corresponding operations on each factor and on product neighbourhoods. ■

Theorem (`mem_pair`). Membership in a pairing is witnessed by factors belonging to each argument.

Proof. By definition. ■

Theorem (`mem_pair_prodNbhd`). A product of sets belongs to a pairing if and only if each factor belongs to the corresponding argument.

Proof. Injectivity of the product of sets. ■

Theorem (`fst_pair`). The first projection of a pairing recovers the left argument.

Proof. Compare via the product-membership characterisation of the pairing. ■

Theorem (`prod_mem_split`). Membership of a product neighbourhood in an ideal element splits as membership of the two products against the opposite masters.

Proof. One direction uses upward closure toward the masters; the converse intersects and recovers the factors. ■

Theorem (`pair_fst_snd`). Pairing the two projections of a product ideal element recovers the element.

Proof. Compare via the splitting law. ■

Theorem (`snd_pair`). The second projection of a pairing recovers the right argument.

Proof. Dual to the first-projection recovery. ■

Theorem (`prod_mem_inl`). The left untagging of a product neighbourhood is a neighbourhood of the left system.

Proof. Unpack the witnessing factors. ■

Theorem (`prod_mem_inr`). The right untagging of a product neighbourhood is a neighbourhood of the right system.

Proof. Unpack the witnessing factors. ■

4.4.3 Product element order isomorphism

Order isomorphism between product ideal elements and pairs of factor ideal elements.

Definition (`prodEquiv`). Ideal elements of a product neighbourhood system are order-isomorphic to pairs of ideal elements of the factors: forward projection sends an element to its two projections, and the inverse pairs them again.

Proof. The round-trip identities are the pairing–projection recovery laws; the order equivalence unpacks membership of product neighbourhoods via the splitting characterisation. ■

Theorem (`prodEquiv.apply`). The isomorphism sends a product ideal element to the pair of its projections.

Proof. By definition. ■

Theorem (`prodEquiv.symm_apply`). The inverse isomorphism sends a pair of ideal elements to their pairing.

Proof. By definition. ■

Theorem (`pair_le_pair_iff`). A pairing approximates another if and only if each factor approximates the corresponding factor.

Proof. Forward, evaluate at products against opposite masters and recover the factors by injectivity; reverse, apply the two inequalities to the witnessing factors of a product neighbourhood. ■

4.4.4 Proposition 3.2 — elements of a product

PROPOSITION 3.2. The construct $\mathcal{D}_0 \times \mathcal{D}_1$ always gives a neighbourhood system where for elements $x, x' \in |\mathcal{D}_0|$ and $y, y' \in |\mathcal{D}_1|$ we have

(i) $\langle x, y\rangle \subseteq \langle x', y'\rangle$ iff $x \subseteq x'$ and $y \subseteq y'$.

Moreover, there is a one-one correspondence between the elements of $|\mathcal{D}_0 \times \mathcal{D}_1|$ and pairs of elements of $|\mathcal{D}_0|$ and $|\mathcal{D}_1|$ since all elements of $|\mathcal{D}_0 \times \mathcal{D}_1|$ are of the form $\langle x, y\rangle$.

Proof: Owing to the disjointness of Δ_0 and Δ_1, we note that for $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$ we have

$$(1)\ X \cup Y \subseteq X' \cup Y' \text{ iff } X \subseteq X' \text{ and } Y \subseteq Y'.$$

Thus, $\{X \cup Y, X' \cup Y'\}$ is consistent in $\mathcal{D}_0 \times \mathcal{D}_1$ iff $\{X, X'\}$ is consistent in $\mathcal{D}_0$ and $\{Y, Y'\}$ is consistent in $\mathcal{D}_1$. In the consistent case we find

$$(2) \qquad (X \cup Y) \cap (X' \cup Y') = (X \cap X') \cup (Y \cap Y'),$$

and so $\mathcal{D}_0 \times \mathcal{D}_1$ is closed under consistent intersection. As $\Delta_0 \cup \Delta_1 \in \mathcal{D}_0 \times \mathcal{D}_1$, it is certainly a neighbourhood system.

It is easy to check by the previous calculations that $\langle x, y\rangle \in |\mathcal{D}_0 \times \mathcal{D}_1|$ if $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$. The proof of 3.2(i) follows directly from the definition and (1).

Suppose $z \in |\mathcal{D}_0 \times \mathcal{D}_1|$. Define as a temporary notation:

$$z_0 = \{X \in \mathcal{D}_0 \mid X \cup \Delta_1 \in z\}, \quad \text{and} \quad z_1 = \{Y \in \mathcal{D}_1 \mid \Delta_0 \cup Y \in z\}.$$

Clearly, both $z_0 \in |\mathcal{D}_0|$ and $z_1 \in |\mathcal{D}_1|$. In view of the formula

$$(3) \qquad (X \cup \Delta_1) \cap (\Delta_0 \cup Y) = X \cup Y,$$

we can calculate that

$$z = \langle z_0, z_1\rangle.$$

Moreover, if $z = \langle x, y\rangle$, then $\langle x, y\rangle_0 = x$ and $\langle x, y\rangle_1 = y$.

The one-one correspondence required is thus established. □

There is more going on in the proof of 3.2 than just a one-one correspondence between elements and pairs. The extra information is best formalized by introducing a notation for mappings.

Theorem (`proposition_3_2`). Pairing is order-equivalent to the product of the factor orders, and every product system admits an order isomorphism between its ideal elements and pairs of factor ideal elements.

Proof. Assemble the pairing order law with the product element order isomorphism. ■

4.4.5 Definition 3.3 — projection mappings

DEFINITION 3.3. *Projection mappings*

$$p_0 : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_0 \quad \text{and} \quad p_1 : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_1$$

are defined as relations where

$$(X \cup Y)\ p_0\ X' \text{ iff } X \subseteq X', \quad \text{and} \quad (X \cup Y)\ p_1\ Y' \text{ iff } Y \subseteq Y'$$

hold for all $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$. Given $f : \mathcal{D}_2 \to \mathcal{D}_0$ and $g : \mathcal{D}_2 \to \mathcal{D}_1$, the *paired mapping*

$$\langle f, g \rangle : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$$

is defined as a relation where

$$Z\ \langle f, g \rangle\ (X \cup Y) \text{ iff } Z\ f\ X \text{ and } Z\ g\ Y$$

holds for all $X \in \mathcal{D}_0$, $Y \in \mathcal{D}_1$, and $Z \in \mathcal{D}_2$. □

Definition (`paired`). The pairing of two approximable maps into the factors of a product is the approximable map into the product that relates a neighbourhood to a product neighbourhood precisely when each component map relates it to the corresponding untagged factor.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity follow from the corresponding axioms of the components together with the product neighbourhood laws. ■

Definition (`proj0`). The left projection from a product system relates a product neighbourhood to a left neighbourhood precisely when the left untagging of the product neighbourhood is contained in that neighbourhood.

Proof. Approximable-map axioms follow from the product neighbourhood structure and left untagging. ■

Theorem (`proj0_rel`). Membership in the left-projection relation is product membership, left neighbourhood membership, and containment of the left untagging.

Proof. By definition. ■

Definition (`proj1`). The right projection from a product system relates a product neighbourhood to a right neighbourhood precisely when the right untagging of the product neighbourhood is contained in that neighbourhood.

Proof. Dual to the left projection. ■

Theorem (`proj1_rel`). Membership in the right-projection relation is product membership, right neighbourhood membership, and containment of the right untagging.

Proof. By definition. ■

Theorem (`paired_rel`). Membership in the paired-map relation is product membership together with the two component relations on the untagged factors.

Proof. By definition. ■

Theorem (`toElementMap_proj0`). The elementwise action of the left projection recovers the first projection of a product ideal element.

Proof. Compare membership via upward closure toward products with the right master, and conversely evaluate at that product. ■

Theorem (`toElementMap_proj1`). The elementwise action of the right projection recovers the second projection of a product ideal element.

Proof. Dual to the left projection. ■

Theorem (`toElementMap_proj0_pair`). The left projection sends a pairing of ideal elements to the left argument.

Proof. Compose the elementwise projection law with recovery of the left factor from a pairing. ■

Theorem (`toElementMap_proj1_pair`). The right projection sends a pairing of ideal elements to the right argument.

Proof. Dual to the left case. ■

Theorem (`toElementMap_paired`). The elementwise action of a paired map is the pairing of the elementwise actions of the components.

Proof. Compare membership by unpacking and reconstructing product neighbourhoods from the two component witnesses. ■

Theorem (`proj0_comp_paired`). Composing the left projection with a paired map recovers the left component.

Proof. Compare elementwise actions using the paired and projection laws. ■

Theorem (`proj1_comp_paired`). Composing the right projection with a paired map recovers the right component.

Proof. Dual to the left case. ■

Theorem (`paired_proj`). Pairing the two projections composed with a map into a product recovers that map.

Proof. Compare elementwise actions using the preceding laws and the pairing–projection recovery. ■

4.4.6 Proposition 3.4 — pairing and projections

PROPOSITION 3.4. The mappings p_0, p_1 and $\langle f, g\rangle$ are approximable mappings, provided f and g are, and we have:

(i) $p_0 \circ \langle f, g\rangle = f$ and $p_1 \circ \langle f, g\rangle = g$.

Moreover, for $z \in |\mathcal{D}_0 \times \mathcal{D}_1|$, we have:

(ii) $p_0(z) = z_0$ and $p_1(z) = z_1$,

in the notation of the proof of 3.2. Further if $h : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$ is any approximable mapping, then

(iii) $h = \langle p_0 \circ h, p_1 \circ h\rangle$.

Moreover, for all $w \in |\mathcal{D}_2|$, we have:

(iv) $\langle f, g\rangle(w) = \langle f(w), g(w)\rangle$,

where again on the right-hand side the notation of the proof of 3.2 is used. □

The proof of this result is left as an exercise. Note the consequence that there is a one-one correspondence between pairs of approximable mappings $f : \mathcal{D}_2 \to \mathcal{D}_0$ and $g : \mathcal{D}_2 \to \mathcal{D}_1$ and mappings $h : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$. It is clear that we generalize all this to products

$$\mathcal{D}_0 \times \mathcal{D}_1 \times \cdots \times \mathcal{D}_{n-1}$$

of several systems.

The product construct also neatly explains functions of several variables. In Exercise 2.19 we used the informal notation

$$f : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2$$

and suggested regarding f as a ternary relation

$$X, Y \; f \; Z.$$

But now with $\mathcal{D}_0 \times \mathcal{D}_1$ given an independent meaning, all we have to do is to regard f as a binary relation with

$$(X, Y) \; f \; Z$$

equivalent to the old relationship. We can also employ an element-wise notation as in $f(\langle x, y\rangle)$, which can more easily be written $f(x, y)$. Similar remarks apply to functions of more than two arguments.

We have discussed several times what it means for a function $f(x)$ to come from an approximable mapping. It is interesting to ask the analogous question for functions of several arguments.

Theorem (`proposition_3_4`). Projections invert pairing; pairing the projections of a map into a product recovers that map; and pairing acts elementwise by pairing the images.

Proof. Assemble the left and right composition laws, the pairing–projection recovery, and the element-wise pairing law. ■

4.4.7 Theorem 3.5 — separate approximability

THEOREM 3.5. An elementwise function

$$f : |D_0 \times D_1| \to |D_2|$$

of two arguments comes from an approximable mapping iff for each fixed $a \in |D_0|$ and each fixed $b \in |D_1|$ the transformations

$$x \mapsto f(x, b) \quad \text{and} \quad y \mapsto f(a, y)$$

come from approximable mappings of one argument.

Proof: As this is the first time we have had to deal with constants in functions, a lemma is useful.

The product $\leftrightarrow$ binary approximable-map correspondence is with the approximable maps of two arguments peer.

Theorem (`theorem_3_5`). Joint approximable maps out of a product correspond bijectively to binary approximable maps, and the correspondence agrees elementwise with pairing.

Proof. Assemble the product–binary equivalence with the elementwise pairing law. ■

4.4.8 Constant approximable map

Constant approximable maps valued at a fixed ideal element.

Definition (`constMap`). The constant approximable map at an ideal element relates a domain neighbourhood to a codomain neighbourhood precisely when the latter belongs to that element.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity follow from the filter axioms of the value. ■

Theorem (`constMap_rel`). Membership in the constant-map relation is domain neighbourhood membership together with membership of the value in the codomain neighbourhood.

Proof. By definition. ■

Theorem (`toElementMap_constMap`). The elementwise action of a constant map is the constant function with that value.

Proof. Compare membership: the forward direction unpacks a witnessing domain neighbourhood; the converse evaluates at the domain master. ■

4.4.9 Lemma 3.6 — constant functions

LEMMA 3.6. Given $b \in |D_1|$, the constant function

$$b : |D_0| \to |D_1|$$

where $b(x) = b$ for all $x \in |D_0|$, comes from the approximable mapping such that

$$X \; b \; Y \quad \text{iff} \quad Y \in b,$$

for all $X \in D_0$ and $Y \in D_1$. □

There is no real confusion here in using "b" both for function and value. Returning, then, to the proof of 3.5, we see that the reason that $x \mapsto f(x, b)$ comes from an approximable mapping is that the mapping in question is the composition of two approximable mappings, namely $f \circ \langle I_{D_0}, b \rangle$. Clearly we can interchange the rôles of D_0 and D_1 to get at $y \mapsto f(a, y)$.

Conversely, assume that both these functions come from approximable mappings no matter the choice of a and b. Clearly the mapping to determine f is the relation from $X \cup Y$ to Z where

$$Z \in f(\uparrow X, \uparrow Y) = f(\uparrow (X \cup Y)).$$

To prove that this determines f we calculate by the formula of Exercise 2.9:

$$\begin{aligned} f(x,y) &= \bigcup\{f(\uparrow X, y) \mid X \in x\} \\ &= \bigcup\{\bigcup\{f(\uparrow X, \uparrow Y) \mid Y \in y\} \mid X \in x\} \\ &= \bigcup\{f(\uparrow X, \uparrow Y) \mid X \in x \text{ and } Y \in y\} \\ &= \bigcup\{f(\uparrow (X \cup Y)) \mid (X \cup Y) \in \langle x, y\rangle\}. \end{aligned}$$

And, again by 2.9, this is what was needed. □

Said more informarily, a function of several arguments is approximable in all the variables *jointly* if it is approximable in each of the variables *separately*.

The type of argument used in 3.5 in the first half of the proof also provides a generalization of 2.6 to functions of several arguments. When we form a function like

$$f(g(x,z,\ldots), h(y,x,\ldots), k(z,w,\ldots), \ldots)$$

from given functions $f, g, h, k, \ldots$; we call the process *substitution*.

Theorem (`lemma_3_6`). The constant approximable map at an ideal element has the membership relation of that element, and acts elementwise as the constant function.

Proof. Assemble the relation characterisation with the elementwise constant law. ■

`Lemma_3_6.lean`

4.4.10 Elementwise substitution

Elementwise action of substituting approximable maps into a joint map out of a product.

Theorem (`substitution_toElementMap`). Composing a joint approximable map with a pairing of two maps, then evaluating elementwise, equals the binary elementwise action of the joint map at the images of the two components.

Proof. Expand by the composition, pairing, and product–binary elementwise laws. ■

```

4.4.11 Proposition 3.7 — closure under substitution

PROPOSITION 3.7. The functions of several arguments between domains coming from approximable mappings are closed under substitution.

Proof: An example will establish the method. Suppose there are four variables involved taking values in domains provided by systems D_0, D_1, D_2, D_3. We might have a substitution like:

$$f(g(x_0, x_1), h(x_1, x_2), k(x_3, x_0, x_2)).$$

Here it might be that the values of the functions inside come from quite other systems; for instance,

$$k : D_3 \times D_0 \times D_2 \to D_4$$

might be possible. By using projections

$$p_i : D_0 \times D_1 \times D_2 \times D_3 \to D_i,$$

where $i < 4$, we can assure that we have several functions all on the same product; thus,

$$k \cdot \langle p_3, p_0, p_2 \rangle : D_0 \times D_1 \times D_2 \times D_3 \to D_4.$$

Now no matter on what domains f is defined, the following composition makes sense:

$$f \circ \langle g \circ \langle p_0, p_1 \rangle, h \circ \langle p_1, p_2 \rangle, k \circ \langle p_3, p_0, p_2 \rangle \rangle;$$

and in fact this is the desired function. Writing it this way makes it clear that the function comes from an approximable mapping: we apply 3.3 (generalized, of course, to products with several terms) to construe the parts between brackets $\langle$ and $\rangle$ as approximable mappings, and then by this trick the composition $\circ$ is the ordinary composition of 2.6. □

It has to be admitted that there is a slight point overlooked in forming products like $D \times D$ with two identical domains. This is discussed in Exercise 3.14, invoking explicit isomorphisms.

The construct that makes the whole theory of domains work so smoothly is the function-space construct: it is possible to regard functions as *objects* which form a domain. Look back at Definition 2.1 and compare it with the original definition of element in 1.6. There are obvious formal similarities, except that filters are sets of neighbourhoods and mappings are sets of pairs of neighbourhoods (relations). But as we saw in 1.10 it is possible to turn the filters into tokens via a simple definition of neighbourhood. We apply the same kind of definition to the mappings.

Theorem (`proposition_3_7`). Substituting approximable maps into a joint map is composition with a pairing, and agrees elementwise with the binary action on the substituted images.

Proof. Assemble the elementwise substitution law. ■

`Proposition_3_7.lean`

```

4.4.12 Step neighbourhoods of maps

Step neighbourhoods of approximable maps, finite intersections of steps, and the pointwise order on maps.

Instance (`instPartialOrderApproximableMap`). Approximable maps are partially ordered by inclusion of their neighbourhood relations.

Proof. Reflexivity, transitivity, and antisymmetry follow from the corresponding properties of implication, with equality of maps by agreement of relations. ■

Definition (`step`). The step neighbourhood at a pair of neighbourhoods is the set of approximable maps relating those neighbourhoods.

Theorem (`mem_step`). Membership in a step is the corresponding relation of the map.

Proof. By definition. ■

Definition (`stepFun`). The step function of a finite list of neighbourhood pairs is the set of maps relating every pair in the list.

Theorem (`mem_stepFun`). Membership in a step function is relation of every listed pair.

Proof. By definition. ■

Theorem (`stepFun_nil`). The empty list yields the universal set of maps.

Proof. There are no pairs to satisfy. ■

Theorem (`stepFun_append`). Concatenation of lists yields the intersection of the corresponding step functions.

Proof. Unpack membership in the concatenated list. ■

Theorem (`stepFun_cons`). Prepending a pair yields the intersection of that step with the step function of the tail.

Proof. Unpack membership in the cons list. ■

Theorem (`stepFun_singleton`). A singleton list recovers the corresponding step.

Proof. Reduce via cons and the empty-list law. ■

Theorem (`step_master_eq`). The step at the two masters is the universal set of maps.

Proof. Every approximable map relates the masters. ■

Theorem (`stepFun_up_closed`). Step functions are upward closed in the pointwise order on maps.

Proof. Relations of a smaller map transport along the inequality. ■

Theorem (`step_inter_right`). Intersection of two steps with the same domain neighbourhood is the step at the intersection of the range neighbourhoods.

Proof. One direction uses intersection on the right for the relation; the converse uses monotonicity toward each factor. ■

Theorem (`step_subset`). Steps nest when the domain neighbourhood shrinks and the range neighbourhood expands.

Proof. Apply monotonicity of the relation. ■

4.4.13 Intersection of range neighbourhoods

The intersection of range neighbourhoods forced by a finite list of domain–range pairs, relative to a master range neighbourhood.

Definition (`interYs`). Relative to a master range neighbourhood, a list of domain–range pairs sends a domain neighbourhood to those master tokens that lie in every listed range whenever the domain neighbourhood is contained in the corresponding domain factor.

Theorem (`interYs_nil`). The empty list returns the master range neighbourhood.

Proof. By definition. ■

Theorem (`interYs_cons`). Prepending a pair intersects the implication-set for that pair with the value on the tail.

Proof. By definition. ■

Theorem (`mem_interYs`). A token belongs to the intersection precisely when it belongs to the master and, for every listed pair containing the domain neighbourhood, belongs to that pair's range.

Proof. By induction on the list. ■

Theorem (`interYs_antitone`). Shrinking the domain neighbourhood enlarges the resulting range intersection.

Proof. Containment hypotheses become harder when the domain neighbourhood grows. ■

Theorem (`interYs_subset_master`). The intersection is always contained in the master.

Proof. Unpack the membership characterisation. ■

Theorem (`interYs_subset_of_mem`). Evaluating at a listed domain factor recovers containment in that pair's range.

Proof. Instantiate the membership characterisation at that pair with reflexive containment. ■

4.4.14 Least map of a step list

The least approximable map forced by a consistent finite list of domain–range neighbourhood pairs, and its minimality among maps in the corresponding step neighbourhood.

Definition (`leastMap`). Given a list of neighbourhood pairs that are neighbourhoods of the respective systems, and a consistency hypothesis that the associated range intersections are always neighbourhoods, the

least map relates a domain neighbourhood to a range neighbourhood precisely when the range intersection for that domain neighbourhood is contained in the range neighbourhood.

Proof. Domain and codomain membership are immediate; the masters relate by containment in the master; intersection on the right uses the consistency hypothesis; monotonicity uses antitonicity of the range intersection. ■

Theorem (`leastMap_rel`). Membership in the least-map relation is domain and range neighbourhood membership together with containment of the range intersection.

Proof. By definition. ■

Theorem (`leastMap_mem_stepFun`). The least map belongs to the step function of its defining list.

Proof. Evaluate the relation at each listed pair using containment of the range intersection in that pair's range. ■

Theorem (`rel_interYs`). Every map in a step function relates a domain neighbourhood to the associated range intersection.

Proof. By induction on the list, using monotonicity and intersection on the right when the domain neighbourhood sits under a listed domain factor. ■

Theorem (`leastMap_le`). The least map is below every map in its step function.

Proof. Transport the range-intersection relation along containment into the target neighbourhood. ■

Theorem (`stepFun_subset_step_iff`). Under consistency, a step function is contained in a step if and only if the associated range intersection is contained in the step's range neighbourhood.

Proof. Forward, evaluate at the least map; reverse, use the range-intersection relation for an arbitrary map in the step function. ■

4.4.15 Definition 3.8 — function space

DEFINITION 3.8. Given neighbourhood systems D_0 and D_1, the *function space* $(D_0 \to D_1)$ is the system whose set of tokens is the set of approximable mappings of Definition 2.1 and whose neighbourhoods are finite non-empty intersections of sets of the form

$$[X, Y] = \{f : D_0 \to D_1 \mid X\, f Y\},$$

where $X \in D_0$ and $Y \in D_1$. □

We have been calling our mappings "approximable" for a long time now without saying exactly how they can be approximated! Definition 3.8 supplies the missing key, because once a domain has been defined, then the general theory gives an explicit meaning to the word approximation. We still have to verify, however, that the mappings do correspond to the elements of the domain.

Definition (`funSpace`). The function space of two neighbourhood systems has as tokens the approximable maps between them, and as neighbourhoods the nonempty step functions of finite lists of neighbourhood pairs from the respective systems, with master the universal set.

Proof. The master is nonempty via the constant map at the bottom; intersection of neighbourhoods concatenates the witnessing lists; every neighbourhood sits in the master. ■

Theorem (`funSpace_master`). The master of a function space is the universal set of maps.

Proof. By definition. ■

Theorem (`funSpace_mem_iff`). A set of maps is a function-space neighbourhood if and only if it is a nonempty step function of neighbourhood pairs.

Proof. By definition. ■

Theorem (`funSpace_mem_up_closed`). Function-space neighbourhoods are upward closed in the pointwise order on maps.

Proof. Unpack as a step function and apply upward closure of step functions. ■

Theorem (`step_mem`). Every step at neighbourhoods of the factor systems is a function-space neighbourhood.

Proof. Realise it as a singleton step function, witnessed nonempty by the constant map at the principal filter of the range neighbourhood. ■

Theorem (`mem_stepFun_iff`). An ideal element of the function space meets a step function if and only if it meets every corresponding step.

Proof. By induction on the list, using intersection and upward closure in the filter of neighbourhoods. ■

4.4.16 Proposition 3.9 — consistent step neighbourhoods

PROPOSITION 3.9. Let neighbourhoods $X_i \in D_0$ and $Y_i \in D_1$ be given for $i < n$. Then the set of $[X_i, Y_i]$ for $i < n$ is consistent in $(D_0 \to D_1)$ iff the following condition holds:

(i) whenever $I \subseteq \{0, 1, \ldots, n-1\}$ and $\{X_i \mid i \in I\}$ is consistent in D_0, then $\{Y_i \mid i \in I\}$ must be consistent in D_1.

Moreover, when consistency holds, the least approximable mapping f_0 belonging to the intersection of the $[X_i, Y_i]$ is defined by:

(ii) $X f_0 Y$ iff $\bigcap\{Y_i \mid X \subseteq X_i\} \subseteq Y$ for $X \in D_0$ and $Y \in D_1$.

Proof: Suppose the $[X_i, Y_i]$ are consistent in $(D_0 \to D_1)$. Since the function space is being defined outright as a positive system, consistency means

$$f \in \bigcap\{[X_i, Y_i] \mid i < n\}$$

for some $f : D_0 \to D_1$. Now, with f in hand, let us check condition (i). Suppose $\{X_i \mid i \in I\}$ is consistent. This means

$$x \in \bigcap\{[X_i] \mid i \in I\}$$

for some $x \in |D_0|$. Suppose $i \in I$, so $x \in [X_i]$. Since $X_i f Y_i$ holds, $f(x) \in [Y_i]$. This means, therefore, that

$$f(x) \in \bigcap\{[Y_i] \mid i \in I\},$$

and so $\{Y_i \mid i \in I\}$ is consistent.

For the converse, suppose (i) is the case. We take (ii) as the definition of a mapping and remark that for an arbitrary $X \in D_0$, the set $\{X_i \mid X \subseteq X_i\}$ is automatically consistent in D_0. By our assumption, the set $\{Y_i \mid X \subseteq X_i\}$ is therefore consistent. This means that

$$\bigcap\{Y_i \mid X \subseteq X_i\} \in D_1.$$

(Keep in mind that i is restricted to those $i < n$, and there are only finitely many neighbourhoods being considered here.) It is thus almost immediate that the relation f_0 defined by (ii) satisfies conditions of 2.1 and so is an approximable mapping $f_0 : D_0 \to D_1$. By construction

$$X_i f_0 Y_i$$

holds trivially for all $i < n$; therefore,

$$f_0 \in \bigcap\{[X_i, Y_i] \mid i < n\}$$

and the desired consistency is established.

Finally suppose that f is any mapping in the neighbourhood under discussion; this means $X_i f Y_i$ holds for all $i < n$. Suppose $X f_0 Y$ holds. We have for $X \subseteq X_i$, $X f Y_i$; so

$$X f \bigcap\{Y_i \mid X \subseteq X_i\} \subseteq Y.$$

Thus, $X f Y$ follows; hence, as relations, $f_0 \subseteq f$. In other words f_0 is the minimal element of the neighbourhood. □

We note that, as a consequence of what we have just proved, when the neighbourhood is consistent, then

$$\bigcap\{[X_i, Y_i] \mid i < n\} \subseteq [X, Y]$$

is exactly equivalent to

$$\bigcap\{Y_i \mid X \subseteq X_i\} \subseteq Y.$$

Note also that a single neighbourhood $[X_0, Y_0]$ is always consistent since it contains the *constant mapping* k where

$$X k Y \text{ iff } Y_0 \subseteq Y,$$

for all $X \in \mathcal{D}_0$ and $Y \in \mathcal{D}_1$. Some other simple observations about these neighbourhoods are just translations of the conditions of Definition 2.1:

$$[\Delta_0, \Delta_1] = |\mathcal{D}_0 \to \mathcal{D}_1|;$$

$$[X, Y] \cap [X, Y'] = [X, Y \cap Y']; \text{ and}$$

$$X' \subseteq X \text{ and } Y \subseteq Y' \text{ imply } [X, Y] \subseteq [X', Y'],$$

for all $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$. We are now ready to prove the main result about the construct.

Theorem (`proposition_3_9`). Under consistency of a finite step list, the least map lies in the corresponding step function, is minimal among maps in that neighbourhood, and containment of the step function in a step is equivalent to containment of the associated range intersection.

Proof. Assemble membership of the least map in the step function, its minimality, and the step-containment equivalence. ■

4.4.17 Function-space element isomorphism

Order isomorphism between ideal elements of a function space and approximable maps.

Definition (`toApproxMap`). An ideal element of a function space determines an approximable map by relating neighbourhoods precisely when the corresponding step belongs to the element.

Proof. Domain and codomain membership unpack a witnessing map in the step; the masters relate via the master step being universal; intersection on the right and monotonicity use the filter axioms with the step intersection and nesting laws. ■

Theorem (`toApproxMap_rel`). Membership in the recovered relation is membership of the corresponding step in the ideal element.

Proof. By definition. ■

Definition (`toFilter`). An approximable map determines an ideal element of the function space consisting of those function-space neighbourhoods that contain the map.

Proof. Filter axioms follow from the neighbourhood structure of the function space and membership of the map. ■

Theorem (`mem_toFilter`). Membership in the filter of a map is function-space neighbourhood membership together with containment of the map.

Proof. By definition. ■

Definition (`funSpaceEquiv`). Ideal elements of a function space are order-isomorphic to approximable maps via the two conversions.

Proof. Round trips compare membership via step-function generation of neighbourhoods; the order equivalence unpacks approximation as containment of steps. ■

Theorem (`funSpaceEquiv_apply`). The isomorphism sends an ideal element to its recovered approximable map.

Proof. By definition. ■

Theorem (`funSpaceEquiv_symm_apply`). The inverse isomorphism sends a map to its principal filter of neighbourhoods containing it.

Proof. By definition. ■

Theorem (`funSpace_mem_inter`). The intersection of two nonempty function-space neighbourhoods is again a neighbourhood.

Proof. Concatenate the witnessing step-function lists. ■

4.4.18 Theorem 3.10 — elements are mappings

THEOREM 3.10. Given neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$, the function space system $(\mathcal{D}_0 \to \mathcal{D}_1)$ is complete in the sense that every filter in $|\mathcal{D}_0 \to \mathcal{D}_1|$ is fixed by a unique approximable mapping.

Proof: Let $f : \mathcal{D}_0 \to \mathcal{D}_1$ be an approximable mapping. By the very definition of $(\mathcal{D}_0 \to \mathcal{D}_1)$ it determines a filter by the definition:

$$\hat{f} = \{F \in (D_0 \to D_1) \mid f \in F\}.$$

Trivially $[X, Y] \in \hat{f}$ iff $f \in [X, Y]$ iff XfY; so this filter uniquely determines the relation f. What we have to show is that every filter in $|D_0 \to D_1|$ is of this form.

Suppose $\varphi \in |D_0 \to D_1|$ is any filter. A relation can be defined at once by

$$X\hat{\varphi}Y \quad \text{iff} \quad [X, Y] \in \varphi.$$

In view of the remarks we made just before stating this theorem, there is no problem in showing that $\hat{\varphi}$ is an approximable mapping. Since the neighbourhoods of the function space are in any case finite intersections of sets like $[X, Y]$, those $[X, Y] \in \varphi$ generate φ. This means that $\hat{\hat{\varphi}} = \varphi$. By definition $\hat{\hat{f}} = f$, so there is a one-one correspondence between mappings and filters. (This correspondence is obviously inclusion preserving, too.) □

We now know just about everything about $|D_0 \to D_1|$ as a domain: the elements correspond isomorphically to the approximable mappings; the finite elements are explained completely by 3.9; and we have seen how to calculate with neighbourhoods. The final step is to relate the function space to other domains by appropriate mappings. In doing this we shall freely construe elements of $|D_0 \to D_1|$ as approximable mappings in view of 3.10.

The function-space element isomorphism is with the function-space element isomorphism peer.

Theorem (`theorem_3_10`). Ideal elements of a function space correspond bijectively and order-preservingly to approximable maps.

Proof. Invoke the function-space element isomorphism. ■

4.4.19 Evaluation combinator

Evaluation of an approximable map at an argument, as a binary approximable map on the function space.

Definition (`eval`). Evaluation relates a function-space neighbourhood, a domain neighbourhood, and a codomain neighbourhood precisely when every map in the former relates the latter two.

Proof. Domain and codomain membership unpack the conjuncts; the masters relate by the masters of each system and the master law for each map; intersection on the right and monotonicity use the corresponding laws for each map in the function-space neighbourhood. ■

Definition (`evalMap`). Evaluation as a joint approximable map out of the product of a function space with its domain is the product form of binary evaluation.

Proof. Apply the product encoding of binary approximable maps. ■

Theorem (`toElementMap2_eval`). Binary evaluation of an ideal element of a function space at an ideal element of the domain recovers application of the corresponding approximable map.

Proof. Compare membership: upward closure with a step neighbourhood yields one inclusion; the converse witnesses evaluation at that step. ■

Theorem (`evalMap_apply`). Joint evaluation at a paired ideal element equals application of the recovered approximable map.

Proof. Unpack the product encoding and apply the binary evaluation identity. ■

Theorem (`toElementMap_evalMap_comp_paired`). Evaluation after pairing a map into a function space with a map into the domain acts elementwise by applying the recovered value of the first to the value of the second.

Proof. Compose the elementwise pairing and evaluation identities. ■

4.4.20 Theorem 3.11 — evaluation combinator

THEOREM 3.11. Given neighbourhood systems D_1 and D_2, there is a uniquely determined approximable mapping

$$\text{eval} : (D_1 \to D_2) \times D_1 \to D_2,$$

where for all $f : D_1 \to D_2$ and all $x \in |D_1|$ we have

(i) $\text{eval}(f, x) = f(x)$.

Proof: For $F \in (D_1 \to D_2)$ and $X \in D_1$ and $Y \in D_2$ define eval as a relation by:

$$F, X \text{ eval } Y \quad \text{iff} \quad X f Y \text{ for all } f \in F.$$

Remember that neighbourhoods in the function space are sets of approximable mappings. It is easily checked that this definition makes eval approximable. We now calculate the function values by the formula of 2.2 (i):

$$\text{eval}(f, x) = \{Y \in D_2 \mid \exists F \in (D_1 \to D_2)\, \exists X \in x.\ f \in F \text{ and } F \cup X \text{ eval } Y\}$$

Because, again by 2.2 (i), we have

$$f(x) = \{Y \in D_2 \mid \exists X \in x.\ X f Y\},$$

we can see from the definition of eval that $\text{eval}(f, x) \subseteq f(x)$. Suppose that $Y \in f(x)$. Then $X f Y$ holds for some $X \in x$. We can write $f \in [X, Y] \in (D_1 \to D_2)$ and it is clear that

$$[X, Y] \cup X \text{ eval } Y$$

holds by definition. Therefore, $Y \in \text{eval}(f, x)$, and so $f(x) \subseteq \text{eval}(f, x)$. □

This theorem is essential for our programme: it shows that in taking functions as objects the very basic operation of forming the function value is an approximable mapping. In other words we can treat the expression $f(x)$ not just as a function of x, as we have done from the start, but also as a function of f as well. The result also indicates that there are useful maps defined on domains that themselves are function spaces; we shall meet many more of these. The next theorem provides further examples.

The evaluation combinator is with the evaluation combinator peer.

Theorem (`theorem_3_11`). Joint evaluation of an ideal element of a function space at an ideal element of the domain equals application of the recovered approximable map.

Proof. Invoke the joint evaluation identity. ■

4.4.21 Currying

Currying and uncurrying for approximable maps, with the adjunction to evaluation.

Definition (`gSection`). Fixing a domain neighbourhood of a product map yields an approximable map on the second factor by relating neighbourhoods precisely when the product neighbourhood of the fixed factor with the second relates under the original map.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity inherit from the product map via the product-neighbourhood laws. ■

Theorem (`gSection_rel`). Membership in a section relation is membership of the corresponding product neighbourhood in the original relation.

Proof. By definition. ■

Theorem (`gSection_le`). Enlarging the fixed domain neighbourhood yields a smaller section.

Proof. Monotonicity of the product map in the product neighbourhood. ■

Definition (`curry`). The curry of a product map relates a domain neighbourhood to a function-space neighbourhood precisely when the section at that neighbourhood belongs to the latter.

Proof. Domain and codomain membership unpack the witnesses; the masters relate by the masters of each system; intersection on the right uses intersection of function-space neighbourhoods; monotonicity uses upward closure and the section comparison. ■

Theorem (`curry_rel`). Membership in the curry relation is domain membership, function-space membership, and section membership.

Proof. By definition. ■

Theorem (`rel_stepFun_iff`). Relating a domain neighbourhood to a step-function neighbourhood is equivalent to relating it to each constituent step.

Proof. By induction on the witnessing list, using the master law, intersection on the right, and monotonicity. ■

Definition (`uncurry`). The uncurry of a map into a function space relates a product neighbourhood to a codomain neighbourhood precisely when the map relates the left projection to the step of the right projection with that codomain neighbourhood.

Proof. Domain membership unpacks the product conjunct; codomain membership unpacks a witnessing map in the step; the masters relate via the product master and the master step; intersection on the right and monotonicity use the corresponding laws for the map into the function space together with step intersection and nesting. ■

Theorem (`uncurry_rel`). Membership in the uncurry relation is product membership together with the projected step relation.

Proof. By definition. ■

Theorem (`curry_uncurry`). Currying after uncurrying recovers the original map into the function space.

Proof. Compare relations via the step-function characterisation. ■

Theorem (`uncurry_curry`). Uncurrying after currying recovers the original product map.

Proof. Compare relations via the product-neighbourhood preimage law. ■

Definition (`curryEquiv`). Product maps are order-isomorphic to maps into the function space via curry and uncurry.

Proof. The round trips are the previous identities; order equivalence unpacks approximation through sections and steps. ■

Theorem (`toElementMap_curry_apply`). Currying acts elementwise by sending a pair of ideal elements to the value of the product map at their pairing.

Proof. Compare membership of codomain neighbourhoods via product neighbourhoods and steps. ■

Theorem (`uncurry_eq`). Uncurry is evaluation after pairing with the projections.

Proof. Compare elementwise via the pairing, projection, and evaluation identities. ■

Theorem (`curry_eval_comp`). Currying evaluation after pairing with the projections recovers the original map into the function space.

Proof. Rewrite via the uncurry equation and the curry–uncurry round trip. ■

Theorem (`eval_comp_curry`). Evaluation after pairing the curry of a product map with the projections recovers that product map.

Proof. Rewrite via the uncurry equation and the uncurry–curry round trip. ■

Theorem (`ApproximableMap.le_iff`). Approximation of approximable maps is pointwise containment of relations.

Proof. By definition. ■

4.4.22 Theorem 3.12 — currying

THEOREM 3.12. Given neighbourhood systems D_0, D_1, D_2 there is associated with every approximable mapping $g : D_0 \times D_1 \to D_2$ a uniquely determined approximable mapping

$$\mathrm{curry}(g) : D_0 \to (D_1 \to D_2)$$

such that for $x \in |D_0|$ and $y \in |D_1|$

(i) $\mathrm{curry}(g)(x)(y) = g(x, y)$.

Moreover we have these functional equations:

(ii) $\text{eval} \circ \langle \text{curry}(g) \circ p_0,\ p_1 \rangle = g$, and

(iii) $\text{curry}(\text{eval} \circ \langle h \circ p_0,\ p_1 \rangle) = h$,

where the $p_i : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_i$ are the projection mappings and $h : \mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2)$ is any approximable mapping. This provides an isomorphism between the domains $|\mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2|$ and $|\mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2)|$ and so we can regard

$$\text{curry} : (\mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2) \to (\mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2))$$

as itself being an approximable mapping.

Proof: Given g as indicated, we can define $\text{curry}(g)$ as a relation and as an approximable mapping by:

$$X\ \text{curry}(g)\ [Y, Z] \text{ iff } X \cup Y\ g\ Z \quad \text{(but see Ex. 3.21)}$$

for all $X \in \mathcal{D}_0$, $Y \in \mathcal{D}_1$, $Z \in \mathcal{D}_2$. This is sufficient because an approximable mapping is intersective in the right-hand neighbourhood, so we know from the above exactly what $X\ \text{curry}(g)\ \bigcap\{[Y_i, Z_i] \mid i < n\}$ means for all finite intersections. The remark after 3.9 is then helpful in checking that by this definition $\text{curry}(g)$ satisfies the monotonicity condition and so is indeed approximable. We now calculate:

$$\begin{aligned}
\text{curry}(g)(x)(y) &= \{Z \in \mathcal{D}_2 \mid \exists Y \in y.\ Y\ \text{curry}(g)\ (x)\ Z\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists Y \in y\ \exists X \in x.\ X\ \text{curry}(g)\ [Y, Z]\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists Y \in y\ \exists X \in x.\ X \cup Y\ g\ Z\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists W \in \langle x, y \rangle.\ W\ g\ Z\} \\
&= g(\langle x, y \rangle) = g(x, y).
\end{aligned}$$

This proves (i). We also see, that if we take the left-hand side of (ii) and apply it to a pair $\langle x, y \rangle$, it reduces to $g(x, y)$ by virtue of (i). Thus, the two functions in (ii) are the same.

Turning to (iii), call the left-hand side k. Using (i) again, we find

$$\begin{aligned}
k(x)(y) &= \text{eval} \circ \langle h \circ p_0, p_1 \rangle(\langle x, y \rangle) \\
&= \text{eval}(\langle h \circ p_0(\langle x, y \rangle), p_1(\langle x, y \rangle) \rangle) \\
&= \text{eval}(\langle h(x), y \rangle) \\
&= h(x)(y).
\end{aligned}$$

As this is true for all $y \in |\mathcal{D}_1|$, then $k(x) = h(x)$ follows. As this is true for all $x \in |\mathcal{D}_0|$, then $k = h$ follows, and (iii) is proved.

Taking (ii) and (iii) together, it is clear that the domains $|D_0 \times D_1 \to D_2|$ and $|D_0 \to (D_1 \to D_2)|$ are in a one-one correspondence.

$$\text{curry}(g) \sqsubseteq \text{curry}(g') \text{ iff } g \sqsubseteq g'.$$

Hence, curry is an isomorphism, and we can invoke 2.7 to conclude that it comes from an approximable mapping. □

We close this lecture with some order-theoretic properties of function spaces that characterize inclusion and upper bounds of functions in a "pointwise" manner.

The currying library is with the currying peer.

Theorem (`theorem_3_12`). Currying acts elementwise by pairing, evaluation after pairing with the projections inverts curry and conversely, and product maps are order-isomorphic to maps into the function space.

Proof. Assemble the elementwise curry law, the two eval/curry equations, and the curry order isomorphism. ■

4.4.23 Pointwise supremum of maps

Pointwise order and bounded supremum of approximable maps.

Definition (`MapsBounded`). A set of approximable maps is bounded when some approximable map dominates every member.

Proof. By definition. ■

Definition (`PointwiseBounded`). A set of approximable maps is pointwise bounded when, at every ideal element of the domain, the set of values is bounded in the codomain.

Proof. By definition. ■

Theorem (`mapsBounded_principal`). Pointwise boundedness implies boundedness of the values at every principal ideal element.

Proof. Specialise pointwise boundedness at the principal. ■

Definition (`supOnPrincipal`). At a domain neighbourhood, the supremum on principals of a pointwise-bounded family is the codomain supremum of the values of the family at that principal.

Proof. Apply the codomain supremum using the principal boundedness. ■

Theorem (`supOnPrincipal_mono`). Shrinking the domain neighbourhood raises the supremum on principals.

Proof. Bound the larger supremum below by comparing values via monotonicity of each map at nested principals. ■

Definition (`sSupMaps`). The pointwise supremum of a pointwise-bounded family is the monotone approximable map determined by the supremum on principals.

Proof. Apply the monotone-to-approximable encoding with the principal-supremum comparison. ■

Theorem (`le_iff_toElementMap_le`). Approximation of approximable maps is equivalent to pointwise approximation of their values.

Proof. Forward, apply a relating neighbourhood at each argument; converse, evaluate at the principal of a relating domain neighbourhood. ■

Theorem (`le_sSupMaps`). Each member of a pointwise-bounded family is below the pointwise supremum.

Proof. A relating neighbourhood of a member belongs to its value at the corresponding principal, hence to the principal supremum. ■

Theorem (`sSupMaps_le`). The pointwise supremum is below every common upper bound of the family.

Proof. Bound the principal supremum by the value of the upper bound at that principal, using pointwise approximation. ■

Theorem (`mapsBounded_iff_pointwiseBounded`). Boundedness of a family of maps is equivalent to pointwise boundedness of its values.

Proof. Forward, apply pointwise approximation at each argument; converse, take the pointwise supremum as a common upper bound. ■

Theorem (`toElementMap_sSupMaps_principal`). The value of the pointwise supremum at a principal is the supremum on that principal.

Proof. Unpack the monotone encoding at principals. ■

Theorem (`toElementMap_sSupMaps`). The value of the pointwise supremum at an ideal element is the codomain supremum of the values of the family there.

Proof. Compare via principals below the argument and the membership of each family member under the pointwise supremum. ■

Theorem (`toElementMap_sSupMaps'`). Under mere boundedness of the family, the same pointwise-supremum identity holds after converting to pointwise boundedness.

Proof. Apply the previous identity via the boundedness equivalence. ■

Theorem (`toFilter_le_iff`). Approximation of maps is equivalent to approximation of their principal filters in the function space.

Proof. Unpack the order isomorphism between maps and function-space elements. ■

Theorem (`mapsBounded_to_filters`). Boundedness of a family of maps implies boundedness of the corresponding filters in the function space.

Proof. The filter of a common upper bound dominates each converted filter. ■

4.4.24 Theorem 3.13 — pointwise order of maps

THEOREM 3.13. For approximable functions $f, g : D_0 \to D_1$ we have

(i) $f \sqsubseteq g$ iff $f(x) \sqsubseteq g(x)$ for all $x \in |D_0|$.

For subsets $F \subseteq |D_0 \to D_1|$ we have

(ii) F is bounded in $|D_0 \to D_1|$ iff $\{f(x) \mid f \in F\}$ is bounded in $|D_1|$ for each $x \in |D_0|$;

and in that case for all $x \in |D_0|$:

(iii) $(\bigsqcup F)(x) = \bigsqcup\{f(x) \mid f \in F\}$.

Proof. The implication in (i) from left to right follows because evaluation is monotone in the function as well as the argument. The converse implication is a consequence of 2.2(ii).

For the proof of (ii) and (iii) we see that by (i) if F is bounded, so is every set $\{f(x) \mid f \in F\}$. For the converse direction, it is clear that (iii) defines *some* pointwise mapping; we have only to prove that it is *approximable*. The calculation that $\sqcup F$ preserves directed unions (see 2.9 and 2.11) is probably the simplest way to reach the conclusion. □

The pointwise-supremum library is with the pointwise supremum of maps peer.

Theorem (`theorem_3_13`). Approximation of approximable maps is pointwise; boundedness of a family is equivalent to pointwise boundedness of values; and the pointwise supremum acts by taking values pointwise.

Proof. Assemble the pointwise-order law, the boundedness equivalence, and the pointwise-supremum identity. ■

4.4.25 Diagonal map

The diagonal approximable map into a product of a system with itself.

Definition (`diag`). The diagonal map of a neighbourhood system is the pairing of the identity with itself.

Proof. By definition. ■

Theorem (`diag_rel`). The diagonal relates a neighbourhood to a product neighbourhood precisely when both projections of that product neighbourhood relate under the identity.

Proof. Unpack the pairing relation. ■

Theorem (`toElementMap_diag`). Elementwise, the diagonal sends each ideal element to its self-pair.

Proof. Apply the pairing and identity evaluations. ■

Theorem (`proj0_comp_diag`). The first projection after the diagonal recovers the identity.

Proof. Invoke the corresponding law for pairing with identities. ■

```

4.4.26 Exercise 3.14 — tagged product of tokens

For the most part we can assume that there is at most a countable number of tokens; thus, without loss of generality the underlying sets Δ_i of given systems $\mathcal{D}_i$ could be assumed to be subsets of Σ^* where $\Sigma = \{0, 1\}$. (Any denumerable set would do.) Show that the product $\mathcal{D}_0 \times \mathcal{D}_1$ could be defined as the system over the set $0\Delta_0 \cup 1\Delta_1$ where

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{0X \cup 1Y \mid X \in \mathcal{D}_0 \text{ and } Y \in \mathcal{D}_1\}.$$

In other words, the assumption of the disjointness of Δ_0 and Δ_1 is unnecessary. Give, therefore, the revised definition of $\langle x, y\rangle$ for elements, and prove that for a single system $\mathcal{D}$, there exists an approximable mapping

$$\mathrm{diag} : \mathcal{D} \to \mathcal{D} \times \mathcal{D}$$

where $\mathrm{diag}(x) = \langle x, x\rangle$ for all $x \in |\mathcal{D}|$. Also extend the definition to a product of n-factors

$$\mathcal{D}_0 \times \mathcal{D}_1 \times \cdots \times \mathcal{D}_{n-1}$$

which will be a system over the set

$$\bigcup_{i<n} 1^i 0 \Delta_i.$$

Note that for a 2-termed product we simplify $10\Delta_1$ to $1\Delta_1$.

The diagonal map is with the diagonal map peer. Tagged products are already realized by the product of systems construction via disjoint union of token types.

Theorem (`example_314`). The first projection recovers the identity after the diagonal.

Proof. Invoke the first-projection law for the diagonal. ■

4.4.27 Product isomorphisms

Usual product isomorphisms, including the empty product as the unit system.

Definition (`prodCommD`). Ideal elements of a product are order-isomorphic to those of the swapped product.

Proof. Transport the cartesian swap of ordered sets through the product-element isomorphism. ■

Definition (`prodCongrOrderIso`). The product of two order isomorphisms is an order isomorphism of products.

Proof. Componentwise application; order equivalence is componentwise. ■

Definition (`prodAssocD`). Ideal elements of a left-associated iterated product are order-isomorphic to those of the right-associated iteration.

Proof. Transport the cartesian associator through the product-element isomorphisms and product congruence. ■

Definition (`prodUniqueOrderIso`). A product with a unique right factor is order-isomorphic to the left factor.

Proof. Project and reinstate the unique default; order comparison ignores the unique coordinate. ■

Definition (`uniqueProdOrderIso`). A product with a unique left factor is order-isomorphic to the right factor.

Proof. Symmetric to the previous. ■

Definition (`unitSys`). The unit neighbourhood system on a singleton has only the universal neighbourhood.

Proof. The filter axioms hold for the unique neighbourhood. ■

Theorem (`unitSys_element_eq`). Every ideal element of the unit system equals the bottom element.

Proof. Compare membership: each neighbourhood of an element contains the master, hence equals the unique neighbourhood. ■

Instance (`Unique unitSys.Element`). The unit system has a unique ideal element.

Proof. The bottom is the unique element by the previous identity. ■

Definition (`prodCongrD`). Ideal elements of products are order-isomorphic when the factors are, via the product of the factor isomorphisms.

Proof. Transport product congruence through the product-element isomorphisms. ■

Definition (`prodUnitD`). Ideal elements of a product with the unit system on the right are order-isomorphic to those of the left factor.

Proof. Apply the unique-right-factor isomorphism after the product-element isomorphism. ■

Definition (`unitProdD`). Ideal elements of a product with the unit system on the left are order-isomorphic to those of the right factor.

Proof. Apply the unique-left-factor isomorphism after the product-element isomorphism. ■

Theorem (`Isomorphic.prod`). Domain isomorphism is congruent under products.

Proof. Unpack witnessing order isomorphisms and apply product congruence. ■

Theorem (`prod_assoc_isomorphic`). Iterated products are associative up to domain isomorphism.

Proof. Invoke the associated element order isomorphism. ■

Theorem (`prod_comm_isomorphic`). Products are commutative up to domain isomorphism.

Proof. Invoke the swapped-product element order isomorphism. ■

Theorem (`prod_unit_isomorphic`). A product with the unit system on the right is isomorphic to the left factor.

Proof. Invoke the corresponding element order isomorphism. ■

Theorem (`unit_prod_isomorphic`). A product with the unit system on the left is isomorphic to the right factor.

Proof. Invoke the corresponding element order isomorphism. ■

4.4.28 Exercise 3.15 — product isomorphisms

Establish the usual isomorphisms:

(i) $\mathcal{D}_0 \times \mathcal{D}_1 \cong \mathcal{D}_1 \times \mathcal{D}_0$;

(ii) $\mathcal{D}_0 \times (\mathcal{D}_1 \times \mathcal{D}_2) \cong (\mathcal{D}_0 \times \mathcal{D}_1) \times \mathcal{D}_2 \cong \mathcal{D}_0 \times \mathcal{D}_1 \times \mathcal{D}_2$.

How does the product of no factors fit in? Prove also:

(iii) $\mathcal{D}_0 \cong \mathcal{D}_0'$ and $\mathcal{D}_1 \cong \mathcal{D}_1'$ imply $\mathcal{D}_0 \times \mathcal{D}_1 \cong \mathcal{D}_0' \times \mathcal{D}_1'$.

The product-isomorphism library is with the product isomorphisms peer. The product of no factors is the unit system there.

Theorem (`example_315`). Products are commutative, congruent under domain isomorphism of factors, and associative, up to domain isomorphism.

Proof. Assemble the commutation, congruence, and association laws. ■

4.4.29 Infinite sequence system

The infinite sequence neighbourhood system, its sequence elements, and the isomorphism with a product.

Definition (`fiber`). The fibre of a set of indexed tokens at an index is the set of tokens appearing with that index.

Proof. By definition. ■

Theorem (`mem_fiber`). Membership in a fibre is membership of the indexed pair in the underlying set.

Proof. By definition. ■

Theorem (`eq_of_fiber_eq`). Two sets of indexed tokens are equal when all fibres agree.

Proof. Compare membership of indexed pairs via the fibres. ■

Theorem (`fiber_inter`). Fibres commute with intersection.

Proof. By definition. ■

Theorem (`fiber_mono`). Fibres preserve inclusion.

Proof. Apply the ambient inclusion to an indexed pair. ■

Definition (`single`). The single-index neighbourhood at an index with a domain neighbourhood is the set of indexed tokens that lie in that neighbourhood at the chosen index and in the master elsewhere.

Proof. By definition. ■

Theorem (`fiber_single_self`). The fibre of a single-index neighbourhood at its own index recovers the domain neighbourhood.

Proof. Unpack the definition at that index. ■

Theorem (`fiber_single_ne`). A fibre of a single-index neighbourhood at a different index is the master.

Proof. Unpack the definition off that index. ■

Definition (`iterSys`). The infinite sequence system consists of those sets of indexed tokens whose fibres are neighbourhoods and that are eventually the master.

Proof. The master is the constant master fibre; intersection preserves fibrewise membership and eventual masters; subsets of neighbourhoods remain below the master fibrewise. ■

Theorem (`iterSys_master`). The master of the sequence system is the set of pairs whose token lies in the base master.

Proof. By definition. ■

Theorem (`fiber_iterSys_master`). Every fibre of the sequence master is the base master.

Proof. By definition. ■

Theorem (`mem_iterSys`). Membership in the sequence system is fibrewise neighbourhood membership together with an eventual master.

Proof. By definition. ■

Theorem (`interUpTo_subset_master`). Finite initial intersections of a sequence of sets in the sequence system lie below the master.

Proof. By induction on the number of factors. ■

Theorem (`reconstruct_subset`). The finite initial intersection of single-index neighbourhoods built from the fibres of a sequence neighbourhood is contained in that neighbourhood.

Proof. On indices below the cutoff, unpack the corresponding single; beyond the cutoff, use the eventual master. ■

Theorem (`single_inter`). Intersection of single-index neighbourhoods at a common index is the single at the intersection of the domains.

Proof. Compare fibres. ■

Theorem (`single_master`). The single-index neighbourhood at the master is the sequence master.

Proof. Compare fibres. ■

Theorem (`single_mem`). A single-index neighbourhood at a neighbourhood is itself a sequence neighbourhood.

Proof. Fibres are the given neighbourhood or the master; after that index they are the master. ■

Theorem (`single_mono`). Singles are monotone in the domain neighbourhood.

Proof. Compare the defining cases. ■

Definition (`component`). The component of a sequence element at an index is the ideal element whose neighbourhoods are those for which the corresponding single belongs to the sequence element.

Proof. Filter axioms follow from those of the sequence element together with the single intersection and nesting laws. ■

Theorem (`mem_component`). Membership in a component is base neighbourhood membership together with membership of the corresponding single in the sequence element.

Proof. By definition. ■

Definition (`ofSeq`). A sequence of ideal elements determines a sequence-system element consisting of those sequence neighbourhoods whose fibres belong to the corresponding terms.

Proof. Filter axioms follow fibrewise from the terms, using fibre intersection and monotonicity. ■

Theorem (`mem_ofSeq`). Membership in the sequence of a family is sequence-neighbourhood membership together with fibrewise membership in the terms.

Proof. By definition. ■

Theorem (`component_ofSeq`). Components of a sequence recover the terms.

Proof. Compare membership via the fibre of the single at the chosen index. ■

Theorem (`ofSeq_mono`). Pointwise approximation of sequences yields approximation of the corresponding sequence elements.

Proof. Apply each term to the corresponding fibre. ■

Theorem (`subset_single`). A sequence neighbourhood is contained in the single built from each of its fibres.

Proof. On the chosen index unpack the fibre; off it use the master bound. ■

Theorem (`ofSeq_component`). Reassembling the components of a sequence element recovers that element.

Proof. One inclusion uses finite reconstruction from singles; the other embeds via singles containing the neighbourhood. ■

Theorem (`le_of_component_le`). Pointwise approximation of components yields approximation of sequence elements.

Proof. Transport through the sequence reconstruction. ■

Definition (`iterSeqEquiv`). Ideal elements of the sequence system are order-isomorphic to arbitrary sequences of base ideal elements.

Proof. The round trips are the component and sequence reconstructions; order equivalence is the pointwise comparison. ■

Definition (`natShiftEquiv`). Sequences are order-isomorphic to a head paired with the tail sequence.

Proof. Split and reassemble by cases on zero; order equivalence compares the head and the shifted terms. ■

Definition (`iterProdIso`). Ideal elements of the sequence system are order-isomorphic to those of the product of the base with the sequence system.

Proof. Compose the sequence isomorphism, the head–tail shift, product congruence, and the product-element isomorphism. ■

Definition (`projN`). Projection at an index relates a sequence neighbourhood to a base neighbourhood precisely when the fibre at that index is contained in the latter.

Proof. Domain and codomain membership unpack the conjuncts; the masters relate by the master fibre; intersection on the right and monotonicity use the base laws with fibre monotonicity. ■

Theorem (`subset_of_fiber_subset`). Fibrewise inclusion implies inclusion of indexed-token sets.

Proof. Apply the fibre inclusion at the index of a pair. ■

Theorem (`projN_rel`). Membership in a projection relation is sequence membership, base membership, and fibre containment.

Proof. By definition. ■

Theorem (`toElementMap_projN`). Projection at an index acts elementwise as the corresponding component.

Proof. Compare membership via singles and fibre containment. ■

Theorem (`iter_isomorphic`). The sequence system is isomorphic to its product with the base.

Proof. Invoke the corresponding element order isomorphism. ■

4.4.30 Exercise 3.16 — infinite sequences of elements

Let $\mathcal{D}$ be a given neighbourhood system over $\Delta \subseteq \Sigma^*$. Define

$$\Delta^\infty = \bigcup_{n=0}^{\infty} 1^n 0 \Delta,$$

so that Δ^∞ is split into infinitely many disjoint copies of Δ. Let $\mathcal{D}^\infty$ be the least family of subsets of Σ^* where

1. $\Delta^\infty \in \mathcal{D}^\infty$, and
2. whenever $X \in \mathcal{D}$ and $Y \in \mathcal{D}^\infty$, then $0X \cup 1Y \in \mathcal{D}^\infty$.

Show that $\mathcal{D}^\infty$ is a neighbourhood system over Δ^∞. Prove the isomorphism

$$\mathcal{D}^\infty \cong \mathcal{D} \times \mathcal{D}^\infty.$$

Show, moreover, that the elements of $|\mathcal{D}^\infty|$ are in a one-one correspondence with arbitrary infinite sequences $\langle x_n \rangle_{n=0}^\infty$ of elements $x_n \in |\mathcal{D}|$ by using combinations of neighbourhoods

$$0X_0 \cup 10X_1 \cup \cdots \cup 1^n 0X_n \cup \cdots,$$

where from some point on all the X_m are equal to Δ.

The infinite sequence system is with the infinite sequence system peer.

Theorem (`example_316`). The infinite sequence system is isomorphic to its product with the base system.

Proof. Invoke the sequence–product isomorphism. ■

4.4.31 Embedding binary sequences

Embedding of binary sequences into the infinite token sequence system, with a left inverse.

Definition (`T`). Write T for the token neighbourhood system of Example 1.2.

Proof. By abbreviation. ■

Definition (`Token`). Write Token for the underlying token type of Example 1.2.

Proof. By abbreviation. ■

Theorem (`T_nbhd_nonempty`). Every neighbourhood in T is nonempty.

Proof. Inspect the three neighbourhoods of Example 1.2. ■

Definition (`bitNbhd`). The bit neighbourhood of a boolean is the zero neighbourhood or the one neighbourhood according as the bit is false or true.

Proof. By definition. ■

Theorem (`bitNbhd_mem`). Each bit neighbourhood belongs to T.

Proof. Invoke the corresponding membership facts of Example 1.2. ■

Definition (`encSet`). The encoding of a finite boolean string is the set of indexed tokens that, whenever the string is defined at that index, lie in the corresponding bit neighbourhood.

Proof. By definition. ■

Theorem (`mem_encSet`). Membership in an encoding is the defining bit constraint at each index.

Proof. By definition. ■

Theorem (`encSet_nil`). The encoding of the empty string is the universal set.

Proof. The defining constraints are vacuous. ■

Theorem (`comparable_of_agree`). Two finite boolean strings that never disagree at a common defined index are comparable under the prefix order.

Proof. By induction on the strings, matching heads when both are nonempty. ■

Theorem (`encSet_agree`). If a sequence neighbourhood is contained in two encodings, then those encodings agree on every commonly defined bit.

Proof. Pick a token from the fibre at that index and observe that it must lie in both bit neighbourhoods. ■

Theorem (`encSet_anti`). Extending a string shrinks its encoding.

Proof. A defined bit of the shorter string remains defined with the same value after concatenation. ■

Theorem (`fiber_encSet_none`). Beyond the length of a string, every fibre of its encoding is universal.

Proof. The defining constraint at that index is vacuous. ■

Theorem (`fiber_encSet_some`). At a defined bit, the fibre of the encoding is the corresponding bit neighbourhood.

Proof. Compare membership of tokens with the defining constraint. ■

Theorem (`encSet_mem`). Every encoding belongs to the infinite sequence system on T.

Proof. Fibres are either the master or a bit neighbourhood; after the string length they are the master. ■

Definition (`f`). The forward embedding relates a cone neighbourhood of a string to a sequence neighbourhood precisely when the encoding of that string is contained in the latter.

Proof. Domain membership recovers cone membership in $\mathcal{B}$; codomain membership is the sequence witness; the masters relate via the empty encoding; intersection on the right uses uniqueness of cones; monotonicity uses anti-monotonicity of encodings under prefixes. ■

Definition (`g`). The reverse map relates a sequence neighbourhood to a cone neighbourhood of a string precisely when the former is contained in the encoding of that string.

Proof. Domain and codomain membership unpack the witnesses; the masters relate via the empty encoding; intersection on the right uses agreement of encodings under a common lower bound together with comparability of agreeing strings; monotonicity uses anti-monotonicity of encodings. ■

Theorem (`exists_not_mem_bitNbhd`). Each bit neighbourhood omits some token.

Proof. The opposite bit token of Example 1.2 lies outside. ■

Theorem (`fg_le_id`). Composing the forward embedding after the reverse map stays below the identity on the sequence system.

Proof. Unpack the composite relation and transport containment through a common encoding. ■

Theorem (`prefix_of_encSet_subset`). Inclusion of encodings implies the reverse prefix order on the corresponding strings.

Proof. Agreeing encodings are comparable; the longer-first case is ruled out by placing a forbidden token at the first undefined index of the shorter string. ■

Theorem (`gf_eq_id`). Composing the reverse map after the forward embedding recovers the identity on $\mathcal{B}$.

Proof. Compare relations: one direction uses the prefix recovery from encodings; the other embeds via the encoding of the larger cone. ■

Theorem (`f_injective`). The forward embedding is injective on ideal elements.

Proof. Apply the left-inverse identity after transporting equality of values through the reverse map. ■

4.4.32 Exercise 3.17 — embedding binary sequences

Using the $\mathcal{B}$ and $\mathcal{T}$ of Example 2.3 show there is a one-one approximable mapping

$$\{f : \mathcal{B} \to \mathcal{T}^\infty\}$$

and another approximable mapping

$$\{g : \mathcal{T}^\infty \to \mathcal{B}\}$$

such that

$$g \circ f = I_{\mathcal{B}} \quad \text{and} \quad f \circ g \subseteq I_{\mathcal{T}^\infty}.$$

Are $\mathcal{B}$ and $\mathcal{T}^\infty$ isomorphic? Are $\mathcal{B}$ and $\mathcal{T} \times \mathcal{B}$ isomorphic?

The embedding and left inverse are with the embedding binary sequences peer.

Theorem (`example_317`). The forward embedding after the reverse map stays below the identity on the sequence system, and the reverse after the forward recovers the identity on $\mathcal{B}$.

Proof. Invoke the corresponding composition laws. ■

4.4.33 Sum system

The separated sum of two neighbourhood systems, with injections and left-inverse projections.

Definition (`il`). The left tag of a token is that token placed in the left summand, then wrapped as a defined optional token.

Proof. By definition. ■

Definition (`inj0`). The left injection of a set is the image of that set under left tagging.

Proof. By definition. ■

Theorem (`il_mem_inj0`). A left-tagged token lies in a left injection precisely when the token lies in the underlying set.

Proof. Unpack the image. ■

Definition (`ir`). The right tag of a token is that token placed in the right summand, then wrapped as a defined optional token.

Proof. By definition. ■

Definition (`inj1`). The right injection of a set is the image of that set under right tagging.

Proof. By definition. ■

Theorem (`ir_mem_inj0`). A right-tagged token never lies in a left injection.

Proof. The tags disagree. ■

Theorem (`none_mem_inj0`). The undefined token never lies in a left injection.

Proof. Left injections contain only left-tagged tokens. ■

Theorem (`ir_mem_inj1`). A right-tagged token lies in a right injection precisely when the token lies in the underlying set.

Proof. Unpack the image. ■

Theorem (`il_mem_inj1`). A left-tagged token never lies in a right injection.

Proof. The tags disagree. ■

Theorem (`none_mem_inj1`). The undefined token never lies in a right injection.

Proof. Right injections contain only right-tagged tokens. ■

Theorem (`inj0_inter`). Left injection commutes with intersection.

Proof. Compare membership by cases on optional tagged tokens. ■

Theorem (`inj0_inter_inj1`). A left injection meets a right injection emptily.

Proof. No optional tagged token can belong to both. ■

Theorem (`inj0_nonempty`). Left injection preserves nonempty sets.

Proof. Map a witness under left tagging. ■

Theorem (`inj0_subset_inj0`). Inclusion of left injections is equivalent to inclusion of the underlying sets.

Proof. Transport membership through left tagging. ■

Theorem (`inj1_inter`). Right injection commutes with intersection.

Proof. Compare membership by cases on optional tagged tokens. ■

Theorem (`inj1_nonempty`). Right injection preserves nonempty sets.

Proof. Map a witness under right tagging. ■

Theorem (`inj1_subset_inj1`). Inclusion of right injections is equivalent to inclusion of the underlying sets.

Proof. Transport membership through right tagging. ■

Definition (`sumMaster`). The sum master is the undefined token together with the left and right injections of the two masters.

Proof. By definition. ■

Theorem (`none_mem_sumMaster`). The undefined token belongs to the sum master.

Proof. It is inserted by definition. ■

Theorem (`il_injective`). Left tagging is injective.

Proof. Optional and summand constructors are injective. ■

Theorem (`il_preimage_inj0`). Preimaging a left injection under left tagging recovers the underlying set.

Proof. Apply injectivity of left tagging. ■

Theorem (`inj0_subset_sumMaster`). The left injection of a neighbourhood lies below the sum master.

Proof. Bound the underlying set by the left master and embed. ■

Theorem (`inj1_subset_sumMaster`). The right injection of a neighbourhood lies below the sum master.

Proof. Bound the underlying set by the right master and embed. ■

Theorem (`ir_injective`). Right tagging is injective.

Proof. Optional and summand constructors are injective. ■

Theorem (`ir_preimage_inj1`). Preimaging a right injection under right tagging recovers the underlying set.

Proof. Apply injectivity of right tagging. ■

Definition (`leftPart`). The left part of a sum set relative to the left system is the set of left tokens that are either present as left tags or belong to the left master whenever a right tag or the undefined token appears.

Proof. By definition. ■

Theorem (`mem_leftPart`). Membership in a left part unpacks as left-tag membership or the master-and-cross-witness clause.

Proof. By definition. ■

Definition (`rightPart`). The right part of a sum set relative to the right system is symmetric to the left part.

Proof. By definition. ■

Theorem (`mem_rightPart`). Membership in a right part unpacks as right-tag membership or the master-and-cross-witness clause.

Proof. By definition. ■

Theorem (`leftPart_inj0`). The left part of a left injection recovers the underlying set.

Proof. Cross witnesses are absent from left injections. ■

Theorem (`leftPart_mono`). Left parts are monotone in the sum set.

Proof. Apply the ambient inclusion to each clause. ■

Theorem (`rightPart_inj1`). The right part of a right injection recovers the underlying set.

Proof. Cross witnesses are absent from right injections. ■

Theorem (`leftPart_inj1`). The left part of a nonempty right injection is the left master.

Proof. A right-tag witness forces the master clause for every left token in the master. ■

Theorem (`leftPart_sumMaster`). The left part of the sum master is the left master.

Proof. The undefined token forces the master clause; left tags recover the left master injection. ■

Theorem (`rightPart_inj0`). The right part of a nonempty left injection is the right master.

Proof. Symmetric to the left-part fact for right injections. ■

Theorem (`rightPart_mono`). Right parts are monotone in the sum set.

Proof. Apply the ambient inclusion to each clause. ■

Theorem (`rightPart_sumMaster`). The right part of the sum master is the right master.

Proof. Symmetric to the left-part fact for the sum master. ■

Theorem (`sumMaster_inter_inj0`). Intersecting the sum master with a left-injected neighbourhood recovers that injection.

Proof. The injection already lies below the sum master. ■

Theorem (`sumMaster_inter_inj1`). Intersecting the sum master with a right-injected neighbourhood recovers that injection.

Proof. The injection already lies below the sum master. ■

Definition (`sum`). Under the standing nonempty-neighbourhood hypotheses, the separated sum consists of the sum master together with all left and right injections of neighbourhoods.

Proof. The master is the sum master; subsets of neighbourhoods stay below it via the injection bounds; intersection is checked by cases on the three kinds of sum neighbourhoods, using emptiness of mixed injections and nonempty fibres to rule out impossible lower bounds. ■

Definition (`inMap0`). The left injection map relates a left neighbourhood to a sum neighbourhood precisely when the left injection of the former is contained in the latter.

Proof. Domain and codomain membership unpack the witnesses; the masters relate by the left-master bound; intersection on the right and monotonicity use the sum intersection law and monotonicity of left injection. ■

Definition (`inMap1`). The right injection map is symmetric to the left injection map.

Proof. Symmetric to the left case. ■

Theorem (`leftPart_mem`). The left part of a sum neighbourhood is a left neighbourhood.

Proof. Case on the three kinds of sum neighbourhoods and apply the left-part identities. ■

Definition (`outMap0`). The left projection relates a sum neighbourhood to a left neighbourhood precisely when the left part of the former is contained in the latter.

Proof. Domain and codomain membership unpack the witnesses; the masters relate by the left-part identity for the sum master; intersection on the right and monotonicity use left-part membership and monotonicity. ■

Theorem (`rightPart_mem`). The right part of a sum neighbourhood is a right neighbourhood.

Proof. Case on the three kinds of sum neighbourhoods and apply the right-part identities. ■

Definition (`outMap1`). The right projection is symmetric to the left projection.

Proof. Symmetric to the left case. ■

Theorem (`inj0_injective`). Left injection of sets is injective.

Proof. Compare inclusions both ways. ■

Theorem (`inj1_injective`). Right injection of sets is injective.

Proof. Compare inclusions both ways. ■

Theorem (`outMap0_comp_inMap0`). The left projection after the left injection recovers the identity on the left system.

Proof. Compare relations via the left-part identity for left injections. ■

Theorem (`outMap1_comp_inMap1`). The right projection after the right injection recovers the identity on the right system.

Proof. Compare relations via the right-part identity for right injections. ■

Theorem (`eq_sumMaster_of_subset`). A sum neighbourhood containing the sum master equals the sum master.

Proof. Apply the master bound in the other direction. ■

Theorem (`mem_subset_inj0`). A sum neighbourhood contained in a left injection is itself a left injection of a left neighbourhood.

Proof. The master and right-injection cases are impossible by tag mismatches. ■

Theorem (`mem_subset_inj1`). A sum neighbourhood contained in a right injection is itself a right injection of a right neighbourhood.

Proof. Symmetric to the left case. ■

Theorem (`not_inj0_subset_inj1`). A nonempty left injection cannot lie below a right injection.

Proof. A left-tagged witness cannot belong to a right injection. ■

Theorem (`not_inj1_subset_inj0`). A nonempty right injection cannot lie below a left injection.

Proof. A right-tagged witness cannot belong to a left injection. ■

4.4.34 Exercise 3.18 — separated sum

Let $\mathcal{D}_0$ and $\mathcal{D}_1$ be neighbourhood systems over Δ_0 and Δ_1, where we again assume that these are subsets of Σ^*. We assume that in addition *no neighbourhood is empty*. Why is this possible without loss of generality?

Define the *sum system* by:

$$\mathcal{D}_0 + \mathcal{D}_1 = \{\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1\} \cup \{0X \mid X \in \mathcal{D}_0\} \cup \{1Y \mid Y \in \mathcal{D}_1\}.$$

Prove that this is a neighbourhood system over $\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1$. (Throwing in $\{\Lambda\}$ was not all that necessary, but note that $\mathcal{B} = \mathcal{B} + \mathcal{B}$, and this is an equality of sets not just an isomorphism of systems.)

Prove that in general there are mappings

$$in_i : \mathcal{D}_i \to \mathcal{D}_0 + \mathcal{D}_1 \quad \text{and} \quad out_i : \mathcal{D}_0 + \mathcal{D}_1 \to \mathcal{D}_i,$$

where $out_i \circ in_i = I_{\mathcal{D}_i}$. Where does the assumption $\emptyset \notin \mathcal{D}_i$ come in? How can these sums be generalized to n-terms? (Hint: As for products use sets $1^i 0\Delta_i$.) Draw some pictures.

The sum system and the injection/projection laws are with the sum system peer.

Theorem (`example_318`). For nonempty-neighbourhood systems, each projection after the corresponding injection recovers the identity.

Proof. Invoke the left and right composition laws. ■

4.4.35 Induced maps

Induced maps of a pair of approximable maps on products and separated sums.

Definition (`sumMap`). The sum of two approximable maps relates a sum neighbourhood to a sum neighbourhood of the targets by sending the sum master to the sum master and routing left and right injections through the corresponding factor maps.

Proof. Domain and codomain membership unpack the witnesses; the masters relate by the sum masters; intersection on the right and monotonicity are checked by cases on the three kinds of sum neighbourhoods, using injectivity of the tagged copies and the impossibility of mixed inclusions. ■

Theorem (`outMap0_comp_sumMap_comp_inMap0`). The left projection after the sum of maps after the left injection recovers the left factor.

Proof. Compare relations via the left-part identities for left injections and the sum master. ■

Theorem (`outMap1_comp_sumMap_comp_inMap1`). The right projection after the sum of maps after the right injection recovers the right factor.

Proof. Compare relations via the right-part identities for right injections and the sum master. ■

Definition (`prodMap`). The product of two approximable maps is the pairing of each factor after the corresponding projection.

Proof. By definition. ■

Theorem (`toElementMap_prodMap`). Elementwise, the product of maps sends a product element to the pair of the factor values at its components.

Proof. Apply the pairing and composition evaluations with the projection laws. ■

Theorem (`toElementMap_prodMap_pair`). Elementwise, the product of maps sends a pair to the pair of the factor values.

Proof. Specialise the previous identity at a pairing. ■

4.4.36 Exercise 3.19 — induced maps on constructs

Suppose we are given systems and approximable mappings

$$f : \mathcal{D}_0 \to \mathcal{D}'_0 \quad \text{and} \quad g : \mathcal{D}_1 \to \mathcal{D}'_1.$$

Prove there are approximable mappings

$$f \times g : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}'_0 \times \mathcal{D}'_1 \quad \text{and} \quad f + g : \mathcal{D}_0 + \mathcal{D}_1 \to \mathcal{D}'_0 + \mathcal{D}'_1$$

such that

(i) $(f \times g)(x, y) = \langle f(x), g(y) \rangle$ for all $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$, and rewrite this as:

(ii) $f \times g = \langle f \circ p_0, g \circ p_1 \rangle$.

In addition prove that

(iii) $out_0 \circ (f + g) \circ in_0 = f$, and

(iv) $out_1 \circ (f + g) \circ in_1 = g$.

Do equations (iii) and (iv) uniquely determine $f + g$?

The product and sum of maps are with the induced maps peer.

Theorem (`example_319_sum`). The left and right projections after the sum of maps after the corresponding injections recover the factor maps.

Proof. Invoke the corresponding composition laws. ■

Theorem (`example_319`). The product of maps acts componentwise on pairs and on product elements.

Proof. Invoke the corresponding elementwise product-map identities. ■

4.4.37 Product functor

Functoriality of the product of approximable maps, and uniqueness of the categorical pairing.

Theorem (`paired_unique`). A map into a product that recovers given factors after the two projections equals the pairing of those factors.

Proof. Rewrite via the projection–pairing round trip. ■

Theorem (`proj_paired`). The projections after a pairing recover the paired factors.

Proof. Invoke the projection laws for pairing. ■

Theorem (`prodMap_comp`). The product of maps preserves composition in each factor.

Proof. Compare elementwise via the product-map evaluation. ■

Theorem (`prodMap_id`). The product of identity maps is the identity on the product.

Proof. Compare elementwise via the product-map evaluation and the pairing of components. ■

4.4.38 Exercise 3.20 — sum and product functors

(For category theorists). Show that the result of 3.19 can be used to prove that $+$ and $\times$ on the category of domains and approximable maps are indeed functors. Show further that $\times$ is the categorical product for this category.

The product functoriality and pairing uniqueness are with the product functor peer.

Theorem (`example_320`). The product of maps preserves composition and identities, and a map into a product is uniquely determined by its projections.

Proof. Invoke the composition law, the identity law, and the pairing uniqueness law. ■

```

4.4.39 Identity of step neighbourhoods

Criterion for equality of step neighbourhoods, via the least map of a singleton step.

Theorem (`interYs_single_not_subset_eq`). If a domain neighbourhood is not contained in the left factor of a singleton step list, the associated intersection of range neighbourhoods is the master.

Proof. The defining constraints are vacuous off that factor. ■

Theorem (`interYs_single_subset_eq`). If a domain neighbourhood is contained in the left factor of a singleton step list, the associated intersection of range neighbourhoods recovers the right factor.

Proof. Unpack the singleton constraint. ■

Theorem (`stepCons`). The intersection of range neighbourhoods for a singleton step list is always a neighbourhood.

Proof. Case on containment in the left factor and apply the previous identities. ■

Definition (`leastStep`). The least map of a singleton step neighbourhood is the least map of the corresponding singleton list.

Proof. By definition, using the consistency law just proved. ■

Theorem (`leastStep_le`). The least map of a step neighbourhood is below every member.

Proof. Specialise the least-map comparison at a singleton. ■

Theorem (`leastStep_mem`). The least map of a step neighbourhood belongs to that neighbourhood.

Proof. Specialise membership of the least map in a step list at a singleton. ■

Theorem (`leastStep_eq_of_step_eq`). Equal step neighbourhoods have equal least maps.

Proof. Compare both ways via membership of each least map in the other neighbourhood. ■

Theorem (`leastStep_rel`). The least map of a step relates neighbourhoods precisely when the associated intersection of range neighbourhoods is contained in the codomain neighbourhood.

Proof. Unpack the least-map relation at a singleton. ■

Theorem (`step_master_right`). A step neighbourhood with master codomain is the universal set of maps.

Proof. Every map relates the domain neighbourhood to the master by monotonicity of the master law. ■

Theorem (`step_eq_univ_iff`). A step neighbourhood is universal precisely when the codomain neighbourhood is the master.

Proof. Forward, the empty least map forces the master below the codomain; converse is the previous identity. ■

Theorem (`step_eq_of_ne_master`). Distinct from the master on the right, equal step neighbourhoods have equal factors.

Proof. Compare least maps and recover the factors from the least-map relation. ■

Theorem (`step_eq_iff`). Two step neighbourhoods agree precisely when both have master codomain, or the factors agree.

Proof. Combine the universal characterisation with the non-master uniqueness. ■

4.4.40 Exercise 3.21 — identity of step neighbourhoods

In the proofs of 3.12 in the definition of curry (g) it is rather cavalierly assumed that the neighbourhood $[Y, Z]$ uniquely determines Y and Z. Show that this is true if $Z \neq \Delta_2$. (Hint: Find explicitly the least of $f \in [Y, Z]$.) Show that if $Z = \Delta_2$ the biconditional stated at the start of the proof is still valid even though Y is not uniquely determined. (Hint: Remember that $\Delta_1\ g\ \Delta_2$ must hold.) For arbitrary pairs of neighbourhoods of $(D_1 \to D_2)$ is there a simple criterion for identity?

The step-neighbourhood criterion is with the identity of step neighbourhoods peer.

Theorem (`example_321`). Two step neighbourhoods agree precisely when both have master codomain or the factors agree; in particular, off the master the factors are unique, and a master codomain yields the universal neighbourhood of maps.

Proof. Invoke the equality criterion, the non-master uniqueness, and the master-codomain identity. ■

4.4.41 Composition combinator

The composition combinator on function spaces, built from evaluation and currying.

Definition (`compApp`). Composition applied to an argument is evaluation of the outer map at the evaluation of the inner map, organised by projections and pairing.

Proof. Assemble evaluation and pairing along the indicated product projections. ■

Definition (`compMap`). The composition combinator is the curry of composition-at-an-argument.

Proof. By definition. ■

Theorem (`toElementMap_compApp`). Elementwise, composition-at-an-argument evaluates the outer map at the value of the inner map.

Proof. Unpack the defining composition of evaluations and projections. ■

Theorem (`toElementMap_compMap_apply`). Elementwise, the composition combinator acts by ordinary composition of the corresponding maps at each argument.

Proof. Apply the curry evaluation identity and the previous identity. ■

Theorem (`toApproxMap_compMap`). The approximable map of a composed pair is the composition of the approximable maps.

Proof. Compare elementwise via the previous identity. ■

4.4.42 Exercise 3.22 — composition combinator

Prove that there is an approximable mapping

$$\text{comp} : (D_1 \to D_2) \times (D_0 \to D_1) \to (D_0 \to D_2)$$

where for all $g : D_1 \to D_2$ and $f : D_0 \to D_1$ we have

$$\mathrm{comp}(g, f) = g \circ f.$$

Show this directly by writing down the neighbourhood relation and by building the mapping up from eval and curry (on suitable domains) using $\circ$ and $\langle , \rangle$. (Hint: Fill in maps in the following sequence of domains:

1. $(D_0 \to D_1) \times D_0 \to D_1$
2. $(D_1 \to D_2) \times ((D_0 \to D_1) \times D_0) \to (D_1 \to D_2) \times D_1$
3. $((D_1 \to D_2) \times (D_0 \to D_1)) \times D_0 \to (D_1 \to D_2) \times D_1$
4. $((D_1 \to D_2) \times (D_0 \to D_1)) \times D_0 \to D_2$
5. $(D_1 \to D_2) \times (D_0 \to D_1) \to (D_0 \to D_2)$.

The maps are of course not uniquely determined, but the shifting of brackets ought to suggest the right choice.)

The composition combinator is with the composition combinator peer.

Theorem (`example_322`). The composition combinator acts by ordinary composition of the corresponding approximable maps, and agrees elementwise with that composition at each argument.

Proof. Invoke the corresponding composition identities. ■

4.4.43 Cartesian closed category

Cartesian closed structure: the curry adjunction and the terminal unit system.

Instance (`Subsingleton (ApproximableMap V unitSys)`). There is at most one approximable map into the unit system.

Proof. Compare elementwise using uniqueness of the unit element. ■

Instance (`Unique (ApproximableMap V unitSys)`). There is a unique approximable map into the unit system, namely the constant at the unique unit element.

Proof. Take the constant map as default and invoke the subsingleton law. ■

Definition (`homAdjunction`). Maps out of a product are order-isomorphic to maps into the function space via curry.

Proof. Invoke the curry equivalence. ■

Definition (`toUnit`). The unique map into the unit system is the default of that unique type.

Proof. By definition. ■

Theorem (`toUnit_unique`). Every map into the unit system equals the unique map.

Proof. Invoke the subsingleton law. ■

4.4.44 Exercise 3.23 — cartesian closed category

(For category theorists.) Show that the results of 3.11 and 3.12 prove that the category of domains and approximable mappings is a *cartesian closed category*. ([41, pp. 95–96] may be consulted for a very brief introduction.) What is the *terminal domain* in this category? What sort of functor is $(D_0 \to D_1)$?

The terminal map and curry adjunction are with the cartesian closed category peer.

Theorem (`example_323`). Every approximable map into the unit system equals the unique map to the unit.

Proof. Invoke uniqueness of the map to the unit. ■

`Exercise_3_23.lean`

```
module

public import DomainTheory.NeighbourhoodSystems.DomainConstructs.cartClosed

4.4.45 Function-space isomorphisms

Function-space isomorphisms for products, infinite sequences, and sums, including distribution of products over sums.

Definition (`funProdEquiv`). Maps into a product are order-isomorphic to pairs of maps into the factors.

Proof. Pair and project via the pairing–projection laws; order equivalence is componentwise. ■

Definition (`funProdIso`). Function-space elements into a product are order-isomorphic to the product of the function spaces.

Proof. Transport the previous equivalence through the function-space element isomorphisms and the product-element isomorphism. ■

Theorem (`funProd_isomorphic`). The function space into a product is isomorphic to the product of the function spaces.

Proof. Invoke the corresponding element order isomorphism. ■

Theorem (`exists_forall_swap`). A sequence neighbourhood belongs fibrewise to the values of a family of maps at an argument if and only if the assembled sequence of values belongs to that neighbourhood.

Proof. Compare fibre membership with membership of indexed pairs. ■

Theorem (`le_of_projComp_le`). Pointwise approximation of projections after maps into the sequence system yields approximation of the maps.

Proof. Compare via the sequence reconstruction from components. ■

Definition (`mapOfSeq`). A sequence of maps into a base determines a map into the sequence system by requiring fibrewise membership of the values.

Proof. Filter axioms follow fibrewise from the terms. ■

Definition (`piCongrOrderIso`). A family of order isomorphisms induces an order isomorphism of dependent products.

Proof. Apply componentwise; order equivalence is componentwise. ■

Theorem (`projComp_mono`). Approximation of maps into the sequence system yields approximation after each projection.

Proof. Apply monotonicity of the projection. ■

Theorem (`toElementMap_mapOfSeq`). Elementwise, a sequence of maps sends an argument to the sequence of its values.

Proof. Compare membership via fibres. ■

Definition (`funIterEquiv`). Maps into the sequence system are order-isomorphic to sequences of maps into the base.

Proof. The round trips are the sequence of projections and the map of a sequence; order equivalence uses the projection comparison. ■

Definition (`funIterIso`). Function-space elements into the sequence system are order-isomorphic to the sequence system on the function space.

Proof. Transport the previous equivalence through the function-space and sequence-element isomorphisms. ■

Theorem (`funIter_isomorphic`). The function space into the sequence system is isomorphic to the sequence system on the function space.

Proof. Invoke the corresponding element order isomorphism. ■

Definition (`copair`). The copairing of two maps into a common codomain relates a sum neighbourhood by routing left and right injections through the corresponding maps.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity follow by cases on sum neighbourhoods. ■

Definition (`copairProj`). The pair of projections of a map out of a sum is the pair of that map after the two injections.

Proof. By definition. ■

Theorem (`prod_mem_nonempty`). Under nonempty-neighbourhood hypotheses on the factors, every product neighbourhood is nonempty.

Proof. Pick witnesses in each projected neighbourhood. ■

Definition (`distribMap`). Distribution of a product over a sum pairs the first projection with the left injection after the second projection.

Proof. Assemble pairing and composition of the product projections with the left injection. ■

Theorem (`copair_comp_inMap0`). The copair after the left injection recovers the left summand map.

Proof. Compare relations via left injections. ■

Theorem (`copair_comp_inMap1`). The copair after the right injection recovers the right summand map.

Proof. Compare relations via right injections. ■

Theorem (`copairProj_copair`). Projecting a copair recovers the original pair of maps.

Proof. Apply the two injection laws. ■

4.4.46 Exercise 3.24 — function-space isomorphisms

Establish some more isomorphisms :

(i) $(D_0 \to (D_1 \times D_2)) \cong (D_0 \to D_1) \times (D_0 \to D_2)$

(ii) $(D_0 \to D_1^{\infty}) \cong (D_0 \to D_1)^{\infty}$

(iii) $D_0 \times (D_1 + D_2) \cong (D_0 \times D_1) + (D_0 \times D_2)$

(iv) $(D_0 + D_1) \to D_2 \cong (D_0 \to D_2) \times (D_1 \to D_2) \ldots$

If some of the above are not true, perhaps at least some mapping relationships can be established.

The function-space isomorphisms and copairing laws are with the function-space isomorphisms peer.

Theorem (`example_324`). The function space into a product is isomorphic to the product of the function spaces.

Proof. Invoke the product function-space isomorphism. ■

Theorem (`example_324_iter`). The function space into the sequence system is isomorphic to the sequence system on the function space.

Proof. Invoke the sequence function-space isomorphism. ■

Theorem (`example_324_distrib`). Copairing after the injections recovers the summand maps, and projecting a copair recovers the original pair.

Proof. Invoke the corresponding copairing laws. ■

4.4.47 Opens form a domain

Open sets of a domain as maps into the Sierpiński system.

Definition (`sierpinski`). The Sierpiński neighbourhood system on a singleton has the empty set and the singleton as neighbourhoods, with master the singleton.

Proof. The filter axioms hold for these two sets. ■

Definition (`mapOfOpen`). An open set of ideal elements determines an approximable map into Sierpiński by relating a domain neighbourhood to the singleton precisely when the corresponding basic open lies in the open set, and relating freely to the empty neighbourhood.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity unpack the open-set axioms. ■

Theorem (`mapOfOpen_rel_empty`). Relating to the empty Sierpiński neighbourhood is domain membership together with membership of some principal in the open set.

Proof. Unpack the defining cases. ■

Definition (`openOfMap`). The open set of a map into Sierpiński consists of those ideal elements for which some principal neighbourhood relates to the singleton.

Proof. By definition. ■

Theorem (`openOfMap_isOpen`). The open set of a map into Sierpiński is open.

Proof. Witness basic opens via relating neighbourhoods. ■

Definition (`openIso`). Open subsets are order-isomorphic to approximable maps into Sierpiński.

Proof. The round trips are the previous constructions; order equivalence compares membership via principals. ■

Definition (`opensReprIso`). Open subsets are order-isomorphic to ideal elements of the function space into Sierpiński.

Proof. Compose the previous isomorphism with the function-space element isomorphism. ■

4.4.48 Exercise 3.25 — opens form a domain

(For topologists.) Recall from Exercises 1.21 and 2.13 on how to regard a domain $|D|$ as a topological space. Using 3.10 show that the family of open subsets of $|D|$ is isomorphic to a domain.

The Sierpiński representation of opens is with the opens form a domain peer.

Theorem (`example_325`). The open set associated to a map into Sierpiński is open.

Proof. Invoke openness of the open-of-map construction. ■

`Exercise_3_25.lean`

```

4.4.49 Conditional combinator

The conditional operator on a domain, its sum-valued variant, and the which map from a separated sum.

Definition (`TD`). Write T for the token neighbourhood system of Example 1.2.

Proof. By abbreviation. ■

Theorem (`Tmem_eq_one`). A neighbourhood contained in the one neighbourhood equals the one neighbourhood.

Proof. Inspect the three neighbourhoods of Example 1.2. ■

Theorem (`Tmem_eq_zero`). A neighbourhood contained in the zero neighbourhood equals the zero neighbourhood.

Proof. Inspect the three neighbourhoods of Example 1.2. ■

Definition (`condGuard`). A conditional guard on a product neighbourhood and a codomain neighbourhood holds according to Scott's three cases on the token factor.

Proof. By definition. ■

Theorem (`cond_components`). A product neighbourhood for the conditional unpacks as a token neighbourhood paired with a product of domain neighbourhoods.

Proof. Unpack the product membership criterion. ■

Theorem (`one_ne_master`). The one neighbourhood is not the master.

Proof. Compare the underlying sets of Example 1.2. ■

Theorem (`zero_ne_master`). The zero neighbourhood is not the master.

Proof. Compare the underlying sets of Example 1.2. ■

Theorem (`condGuard_master`). A guard with master token factor forces the codomain neighbourhood to be the master.

Proof. Apply the master case of the guard. ■

Theorem (`zero_ne_one`). The zero and one neighbourhoods are distinct.

Proof. Compare the underlying sets of Example 1.2. ■

Theorem (`condGuard_one`). A guard with one token factor reduces to containment of the first domain neighbourhood in the codomain.

Proof. Apply the one case of the guard. ■

Theorem (`condGuard_zero`). A guard with zero token factor reduces to containment of the second domain neighbourhood in the codomain.

Proof. Apply the zero case of the guard. ■

Definition (`cond`). The conditional relates a product neighbourhood of the token system with a product of a domain with itself to a domain neighbourhood precisely when the conditional guard holds.

Proof. Domain and codomain membership unpack the witnesses; the masters relate by the master guard; intersection on the right and monotonicity follow by cases on the token factor. ■

Theorem (`cond_bot`). The conditional at bottom returns bottom.

Proof. Compare membership via the master token factor. ■

Theorem (`cond_false`). The conditional at false returns the second argument.

Proof. Compare membership via the zero token factor. ■

Theorem (`cond_toElementMap_mem`). Membership of the conditional value in a neighbourhood unpacks according to the three token cases.

Proof. Apply the guard characterisation at principals. ■

Theorem (`cond_true`). The conditional at true returns the first argument.

Proof. Compare membership via the one token factor. ■

Theorem (`Tmem_ge_master`). Every neighbourhood of the token system is contained in the master.

Proof. Apply the master bound. ■

Theorem (`Tmem_ge_one`). A neighbourhood contained in the one neighbourhood equals the one neighbourhood or is handled by the containment criterion.

Proof. Inspect the three neighbourhoods. ■

Theorem (`Tmem_ge_zero`). Symmetric to the one case for the zero neighbourhood.

Proof. Inspect the three neighbourhoods. ■

Definition (`condSumEmb`). The sum-valued conditional embedding pairs a token with the left and right injections of the two arguments.

Proof. Assemble pairing with the injections. ■

Definition (`condSum`). The sum-valued conditional is the conditional of the sum after the sum-valued embedding.

Proof. By definition. ■

Theorem (`inter_in_oneset`). Intersection of neighbourhoods from the master–one family stays in that family.

Proof. Case on the two possibilities. ■

Theorem (`inter_in_zeroset`). Intersection of neighbourhoods from the master–zero family stays in that family.

Proof. Case on the two possibilities. ■

Definition (`whichGuard`). A which-guard relates a sum neighbourhood to a token neighbourhood by the three cases distinguishing left injections, right injections, and the sum master.

Proof. By definition. ■

Theorem (`whichGuard_left`). A left-injection guard forces the token neighbourhood into the master–one family.

Proof. Unpack the left case. ■

Theorem (`whichGuard_masterC`). A sum-master guard forces the token neighbourhood to be the master.

Proof. Unpack the master case. ■

Theorem (`whichGuard_right`). A right-injection guard forces the token neighbourhood into the master–zero family.

Proof. Unpack the right case. ■

Definition (`whichMap`). The which map relates a sum neighbourhood to a token neighbourhood precisely when the which-guard holds.

Proof. Domain and codomain membership, master, intersection on the right, and monotonicity follow by cases on sum neighbourhoods. ■

Theorem (`condSumEmb_toElementMap`). Elementwise, the sum-valued embedding pairs a token with the two injections.

Proof. Unpack the defining pairing. ■

Theorem (`condSum_bot`). The sum-valued conditional at bottom returns bottom.

Proof. Rewrite via the embedding and the ordinary conditional at bottom. ■

Theorem (`condSum_false`). The sum-valued conditional at false returns the right injection of the second argument.

Proof. Rewrite via the embedding and the ordinary conditional at false. ■

Theorem (`condSum_true`). The sum-valued conditional at true returns the left injection of the first argument.

Proof. Rewrite via the embedding and the ordinary conditional at true. ■

Theorem (`not_sum_mem_empty`). The empty set is not a sum neighbourhood.

Proof. Each of the three kinds of sum neighbourhood is nonempty under the standing hypotheses. ■

Theorem (`inMap0_outMap0_eq_of_left`). On left summands, the left injection after the left projection recovers the element.

Proof. Compare membership via left injections and left parts. ■

Theorem (`inMap1_outMap1_eq_of_right`). On right summands, the right injection after the right projection recovers the element.

Proof. Compare membership via right injections and right parts. ■

Theorem (`sum_element_trichotomy`). Every sum element is a left summand, a right summand, or bottom.

Proof. Case on membership of distinguishing neighbourhoods. ■

Theorem (`which_mem_one`). The which value of a left summand belongs to the one neighbourhood.

Proof. Apply the left case of the which-guard. ■

Theorem (`which_mem_zero`). The which value of a right summand belongs to the zero neighbourhood.

Proof. Apply the right case of the which-guard. ■

Theorem (`cond_which`). Conditioning on which, with the two reinjected projections, recovers every sum element.

Proof. Case on the trichotomy and apply the conditional and injection–projection laws. ■

4.4.50 Exercise 3.26 — conditional combinator

Show that for every domain D there is an approximable mapping

$$\mathrm{cond} : T \times D \times D \to D,$$

called the *conditional operator*, satisfying

(i) $\mathrm{cond}(\mathrm{true}, x, y) = x$

(ii) $\mathrm{cond}(\mathrm{false}, x, y) = y$

(iii) $\mathrm{cond}(\bot, x, y) = \bot$.

(Hint: Recalling that $T = \{\{0\}, \{1\}, \{0, 1\}\}$, define cond as a relation by

$$\begin{aligned} 0C \cup 10X \cup 110Y \ \mathrm{cond}\ Z \quad \text{iff} \quad & 0 \in C \text{ and } X \subseteq Z \text{ or} \\ & 1 \in C \text{ and } Y \subseteq Z \text{ or} \\ & 0, 1 \in C \text{ and } \Delta \subseteq Z, \end{aligned}$$

where $C \in T$ and $X \in D$ and $Y \in D$ and where we are using the construction of Exercise 3.14.) Find a similar operator in the domain

$$T \times D_0 \times D_1 \to D_0 + D_1.$$

Show also there is an approximable mapping

$$\mathrm{which} : D_0 + D_1 \to T$$

such that for all $x \in |D_0 + D_1|$

$$\mathrm{cond}(\mathrm{which}(x), \mathrm{in}_0(\mathrm{out}_0(x)), \mathrm{in}_1(\mathrm{out}_1(x))) = x.$$

The conditional, sum-valued conditional, and which map are with the conditional combinator peer.

Theorem (`example_326`). The conditional returns the first argument at true, the second at false, and bottom at bottom.

Proof. Invoke the corresponding conditional evaluation laws. ■

Theorem (`example_326_sum`). The sum-valued conditional returns the reinjected arguments at true and false and bottom at bottom, and conditioning on which recovers every sum element.

Proof. Invoke the corresponding sum-conditional and which laws. ■

4.4.51 Function space via closure

Approximable maps as a directed-complete family of graphs, yielding a representation of the function space.

Definition (`graph`). The graph of an approximable map is the set of related pairs of neighbourhoods.

Proof. By definition. ■

Theorem (`mem_graph`). Membership in a graph is the relating relation.

Proof. By definition. ■

Definition (`C`). The family of graphs is the range of the graph map.

Proof. By definition. ■

Theorem (`C_nonempty`). The family of graphs is nonempty.

Proof. The constant map at bottom supplies a graph. ■

Theorem (`graph_injective`). Distinct approximable maps have distinct graphs.

Proof. Extensionality of relations. ■

Definition (`graphEquiv`). Approximable maps are order-isomorphic to their graphs as members of the family of graphs.

Proof. The round trip chooses a witnessing map; order equivalence is inclusion of graphs. ■

Definition (`joinMap`). The directed join of a nonempty directed family of graphs is the approximable map whose relation is the union of the graphs.

Proof. Filter axioms follow by directedness, picking a common upper graph. ■

Definition (`meetMap`). The meet of a nonempty family of graphs is the approximable map whose relation is the intersection of the graphs.

Proof. Filter axioms hold pointwise in the family. ■

Theorem (`sInter_eq_graph_meetMap`). The intersection of a nonempty family of graphs is the graph of the meet map.

Proof. Compare membership. ■

Theorem (`C_inter`). The family of graphs is closed under nonempty intersections.

Proof. The intersection is the graph of the meet. ■

Theorem (`sUnion_eq_graph_joinMap`). The union of a nonempty directed family of graphs is the graph of the join map.

Proof. Compare membership. ■

Theorem (`C_dir`). The family of graphs is closed under nonempty directed unions.

Proof. The union is the graph of the join. ■

Definition (`funSpaceReprIso`). Ideal elements of the representation system on the family of graphs are order-isomorphic to function-space elements.

Proof. Compose the representation isomorphism, the graph equivalence, and the function-space element isomorphism. ■

4.4.52 Exercise 3.27 — function space via closure

(For set theorists.) Give another proof that the family of approximable mappings $f : D_0 \to D_1$ is isomorphic to a domain by employing the general argument of Exercise 2.22. How does this compare with the proof method of 3.9 and 3.10? Can the general remarks also be employed to show that

$$\mathrm{eval} : (D_1 \to D_2) \times D_1 \to D_2$$

is approximable without bringing in the neighbourhoods in such an explicit way? (Hint: Use 3.5 and the idea of Exercise 2.12.)

The graph-closure representation is with the function space via closure peer.

Theorem (`example_327`). The family of graphs is closed under nonempty directed unions.

Proof. Invoke directed-union closure for the family of graphs. ■

4.4.53 Minimal step function

Elementwise characterisation of the least map of a step list as a pointwise supremum of principals.

Definition (`leastMapVals`). At an ideal element, the value set of a step list is the set of principals of those right factors whose left factors contain the argument.

Proof. By definition. ■

Theorem (`Element.mem_interYs_of`). Membership of an ideal element in an intersection of range neighbourhoods is membership in the master together with membership in each active right factor.

Proof. Unpack the defining quantification. ■

Theorem (`leastMap_toElementMap_le_of_ub`). The least map of a consistent step list is below every map that relates each listed pair.

Proof. Bound the value via the relating neighbourhoods of the upper bound. ■

Theorem (`val_le_leastMap_toElementMap`). Each principal arising from an active right factor lies below the value of the least map.

Proof. The least map relates the corresponding left factor to that right factor. ■

Theorem (`leastMapVals_bounded`). Under consistency of the step list, the value set at each argument is bounded.

Proof. The value of the least map is a common upper bound. ■

Theorem (`toElementMap_leastMap_eq_sSup`). The value of the least map at an argument is the supremum of the corresponding value set.

Proof. The least map is an upper bound, and every upper bound of the step list dominates that supremum. ■

4.4.54 Exercise 3.28 — minimal step function

In the function space $(D_0 \to D_1)$ let

$$\bigcap\{[X_i, Y_i] \mid i < n\}$$

be a (non-empty) neighbourhood. In 3.9 the minimal element of this neighbourhood is characterized as a relation f_0. Show that as an elementwise mapping it can be defined by the formula

$$f_0(x) = \bigsqcup\{\uparrow Y_i \mid x \in [X_i]\},$$

for $x \in |D_0|$. Try to draw a picture of $|D_0|$ with neighbourhoods $[X_i]$ and the corresponding values of the function f_0.

The pointwise supremum characterisation is with the minimal step function peer.

Theorem (`example_328`). The value of the least map of a consistent step list at an argument is the supremum of the principals of the active right factors.

Proof. Invoke the pointwise-supremum identity for the least map. ■

4.5 Fixed points and recursion

<!DOCTYPE svg PUBLIC “-//W3C//DTD SVG 1.1//EN” “http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd”>

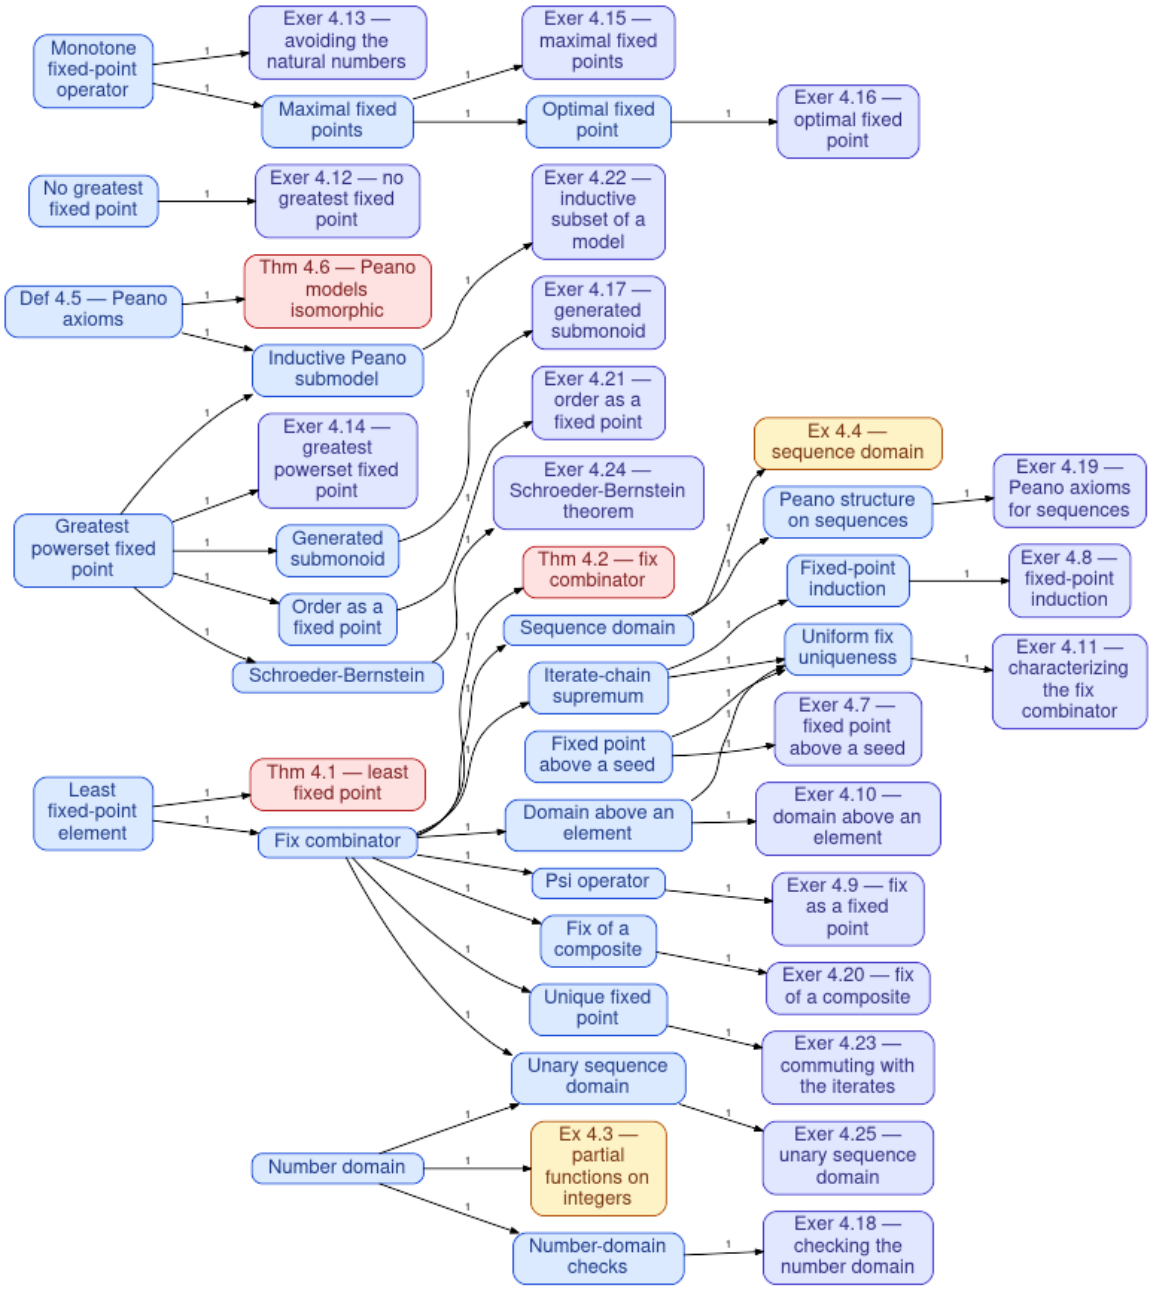

Figure 49: Diagram 14

4.5.1 Introduction

Having at this point a large supply of examples of domains (and further constructs of new domains), we now have to consider some other ways of defining functions — other than by explicit compositions of the very basic functions already mentioned. One of the most fruitful techniques is an infinitely iterated composition that is at the back of the idea of recursion. We will use the process over and over again in these lectures, not only to define new functions but also to define new domains. The heart of the matter lies in the so-called

"Fixed-point Theorem":

4.5.2 Least fixed-point element

Iterates of an endomap and the least fixed-point element they generate.

Definition (`iterMap`). The iterates of an approximable endomap are the identity at stage zero and composition of the map with the preceding iterate at each successor stage.

Proof. By recursion on the stage. ■

Theorem (`iterMap_zero`). The zero-th iterate is the identity map.

Proof. By definition. ■

Theorem (`iterMap_succ`). The successor iterate is the map composed with the preceding iterate.

Proof. By definition. ■

Theorem (`comp_mono`). Composition of approximable endomaps is monotone in each factor.

Proof. Unpack a composite relation into an intermediate neighbourhood and apply the two inequalities. ■

Theorem (`iterMap_mono_map`). Larger endomaps have larger iterates at every stage.

Proof. Induct on the stage, using monotonicity of composition at successor steps. ■

Theorem (`iter_comm`). An endomap commutes with each of its iterates under composition.

Proof. Induct on the stage, using the unit laws for the identity and associativity of composition. ■

Theorem (`rel_master_succ`). A neighbourhood related to the master by an iterate remains related after one further iterate.

Proof. Rewrite the successor iterate via the commutation law and insert the master-to-master relation of the map. ■

Theorem (`rel_master_mono`). Master-relatedness under iterates is preserved when the stage increases.

Proof. Induct along the inequality of stages, using the successor step. ■

Definition (`fixElement`). The least fixed-point element of an endomap consists of those neighbourhoods related to the master by some iterate of the map.

Proof. The master belongs via the identity iterate; upward closure uses monotonicity of the relation; intersection closure equalises stages by the master-relatedness monotonicity and closes under the right-intersection law of the iterate. ■

Theorem (`mem_fixElement`). Membership in the least fixed-point element is existence of a witnessing iterate relating the master to the neighbourhood.

Proof. By definition. ■

Theorem (`fixElement_mono`). Larger endomaps have larger least fixed-point elements.

Proof. Apply monotonicity of iterates stagewise. ■

Theorem (`fixElement_le_of_toElementMap_le`). If the map sends an ideal element into itself, then the least fixed-point element lies below that element.

Proof. Show by induction on the stage that every neighbourhood related to the master by an iterate belongs to the given upper bound, using the identity case for the master and the postfixedness hypothesis at successors. ■

Theorem (`toElementMap_fixElement`). The least fixed-point element is a fixed point of the endomap.

Proof. Compare membership: a neighbourhood reached by a positive iterate witnesses membership after applying the map, and conversely a successor witness unpacks to a related neighbourhood already in the fixed-point element; the zero stage recovers the master via the master relation. ■

4.5.3 Theorem 4.1 — least fixed point

THEOREM 4.1. For any approximable mapping $f : D \to D$ on any domain, there exists a least element $x \in |D|$ where

$$f(x) = x.$$

Proof: Let f^n for $n \in \mathbf{N}$ stand for the n-fold composition of f with itself. That is,

$$f^0 = I_D, \text{ and}$$

$$f^{n+1} = f \circ f^n.$$

Define

$$x = \{X \in D \mid \Delta \; f^n \; X, \text{ for some } n \in \mathbf{N}\}.$$

We see $X \in x$ iff there is a finite sequence $\Delta = X_0, X_1, \ldots, X_n = X$ where $X_i \; f \; X_{i+1}$ holds for all $i < n$. Now since $\Delta \; f \; \Delta$ automatically holds, a sequence for an $X \in x$ can always be extended to a longer sequence just by adding more Δ's on the front.

We want to prove $x \in |D|$. Clearly $\Delta \in x$; and if $X \subseteq Y$ and $X \in x$, then $Y \in x$. All that remains to be shown is the closure of x under intersection. Note that if

$$U \; f \; V \quad \text{and} \quad U' \; f \; V'$$

hold and U, U' are consistent in D, then V and V' are consistent and
$(U \cap U') \; f \; (V \cap V')$
must hold. Generalizing this to sequences, if

$$\Delta = X_0 \; f \; X_1 \; f \; \cdots \; f \; X_n = X, \text{ and}$$

$$\Delta = Y_0 \; f \; Y_1 \; f \; \cdots \; f \; Y_n = Y$$

both hold (and note we have arranged the lengths of the two sequences to be equal), then each pair X_i, Y_i is consistent and we have

$$\Delta = (X_0 \cap Y_0) \; f \; (X_1 \cap Y_1) \; f \; \cdots \; f \; (X_n \cap Y_n) = X \cap Y.$$

This establishes the desired closure.

We also note that if $X \in x$ and $X \; f \; Y$ then $Y \in x$. Therefore, $f(x) \subseteq x$ and indeed by its very construction x is the *least* element of $|D|$ with this property. (Why?) But f is monotone, so $f(f(x)) \subseteq f(x)$; hence, $x = f(x)$. By what we have already said it must be the least such element. □

Because the element we have shown to exist in 4.1 is a least element, it is unique. That is, we have associated with each $f : D \to D$ a special element $x_f \in |D|$ determined by the choice of f. A function has therefore been defined mapping the set $|D \to D|$ into $|D|$. The next result shows that this function, or operator on functions, is in fact approximable.

The least fixed-point construction and its fixed-point / leastness laws are with the least fixed-point element peer.

Theorem (`theorem_41`). Every approximable endomap has a least fixed point: its least fixed-point element is fixed by the map and lies below every postfixed point.

Proof. Invoke the fixed-point law and the leastness law for the least fixed-point element. ■

4.5.4 Fix combinator

The fix combinator as an approximable map on the function space, characterised as a directed supremum of iterates from bottom.

Definition (`fixMap`). The fix combinator sends each function-space neighbourhood to the least fixed-point element of its principal map, and extends by the monotone-extension principle to an approximable map from the function space into the domain.

Proof. Monotonicity of the assignment on principals follows from monotonicity of least fixed-point elements under the function-space order isomorphism. ■

Definition (`iterElem`). The n-th iterate element of an endomap is the elementwise action of the n-th iterate map on the bottom element.

Proof. By definition. ■

Theorem (`exists_principal_iterMap`). If an iterate of the recovered map relates the master to a neighbourhood, some neighbourhood of the function-space element has the same relation for the principal of that neighbourhood.

Proof. Induct on the stage: the master neighbourhood works at stage zero; at a successor, intersect the inductive neighbourhood with the witnessing step and compare iterates by monotonicity. ■

Theorem (`fixMap_toElementMap_principal`). On a principal function-space element, the fix combinator evaluates to the least fixed-point element of the recovered principal map.

Proof. Invoke the evaluation law for the monotone extension on principals. ■

Theorem (`fixMap_toElementMap`). On an arbitrary function-space element, the fix combinator evaluates to the least fixed-point element of the recovered map.

Proof. Compare membership via the principal-witness characterisation of the elementwise image, using monotonicity of least fixed-point elements one way and the principal-iterate existence lemma the other. ■

Theorem (`fixMap_least`). If the recovered map sends an ideal element into itself, the value of the fix combinator lies below that element.

Proof. Rewrite via the evaluation law and apply leastness of the least fixed-point element. ■

Theorem (`toElementMap_fixMap`). The value of the fix combinator is a fixed point of the recovered map.

Proof. Rewrite via the evaluation law and apply the fixed-point law for the least fixed-point element. ■

Theorem (`fixMap_toElementMap_toFilter`). On the principal filter of an endomap, the fix combinator recovers that map's least fixed-point element.

Proof. Rewrite via the evaluation law and cancel the round trip through the function-space isomorphism. ■

Theorem (`iterElem_eq_iterate`). Iterate elements agree with ordinary iteration of the elementwise map on the bottom element.

Proof. Induct on the stage, using the identity law at zero and the composition law for elementwise images at successors. ■

Theorem (`mem_iterElem`). Membership in an iterate element is master-relatedness under the corresponding iterate map.

Proof. Unpack the elementwise image of bottom, whose only neighbourhood is the master. ■

Theorem (`iterElem_mono`). Iterate elements increase with the stage.

Proof. Transport master-relatedness monotonicity of iterates through the membership characterisation. ■

Theorem (`fixElement_eq_iSupDirected`). The least fixed-point element is the directed supremum of the iterate elements.

Proof. Compare membership with the directed-supremum membership law via the iterate-element characterisation. ■

Theorem (`fixMap_eq_iSup`). The value of the fix combinator is the directed supremum of the iterate elements of the recovered map.

Proof. Rewrite via the evaluation law and apply the directed-supremum characterisation of the least fixed-point element. ■

Theorem (`fixMap_fixed`). The value of the fix combinator is a fixed point of the map recovered from each function-space element.

Proof. Rewrite via the evaluation law and apply the fixed-point law for the least fixed-point element of the recovered map. ■

Theorem (`fixMap_unique`). Any approximable map on the function space that is fixed-point and least on each principal agrees with the fix combinator.

Proof. Compare below using the fix combinator's fixed-point and leastness laws against the assumed laws pointwise on principals. ■

4.5.5 Theorem 4.2 — fix combinator

THEOREM 4.2. For any domain D, there is an approximable mapping

$$\mathrm{fix} : (D \to D) \to D$$

such that if $f : D \to D$ is any approximable mapping, then

(i) $\mathrm{fix}(f) = f(\mathrm{fix}(f))$.

Furthermore, if $x \in |D|$, then

(ii) $f(x) \subseteq x$ implies $\mathrm{fix}(f) \subseteq x$.

And this last property implies that fix is unique. Explicitly we can characterize fix by the equation:

(iii)

$$\mathrm{fix}(f) = \bigcup_{n=0}^{\infty} f^n(\bot),$$

for all $f : D \to D$.

Proof: Formula (iii) can be put in a more elementary form:

$$\mathrm{fix}(f) = \{X \mid \Delta f^n X, \text{ for some } n \in \mathbf{N}\}.$$

To show an elementwise mapping approximable we can use the formula of Exercise 2.9, applied to the above as the definition of fix:

$$(*) \quad \mathrm{fix}(f) = \bigcup\{\mathrm{fix}(\uparrow F) \mid f \in [F]\},$$

where F ranges over the neighbourhoods of $(D \to D)$, and where $\uparrow F$ can be considered to be the least element of F as calculated in 3.9.

Now from the definition of fix, it is clear that whenever $f \subseteq g$, then $\mathrm{fix}(f) \subseteq \mathrm{fix}(g)$, because $f^n \subseteq g^n$. (That is, fix is obviously monotone.) Next, if $f \in F$, then $\uparrow F$ is a (finite) approximation to f; so $\uparrow F \subseteq f$ and $\mathrm{fix}(\uparrow F) \subseteq \mathrm{fix}(f)$. This means that half of equation (*) already holds by monotonicity. All that is left is to prove the other half.

So suppose $X \in \mathrm{fix}(f)$. Then, as we have already remarked, there is a finite sequence of neighbourhoods where

$$\Delta = X_0 \; f \; X_1 \; \ldots \; X_{n-1} \; f \; X_n = X.$$

Let the function-space neighbourhood be defined as

$$F = \bigcap \{[X_i, X_{i+1}] \mid i < n\},$$

and note that since $f \in [F]$ we have at once consistency. But, by 3.9, $\uparrow F \in [F]$, so the *same* sequence of X_i is sufficient to show that

$$X \in \mathrm{fix}(\uparrow F).$$

In other words, if X belongs to the left-hand side of (*), it also belongs to the right-hand side. This completes the proof of (*).

Formula (i) is just a restatement of what we proved in 4.1. And (ii) follows easily, because $f(x) \subseteq x$ implies that $\Delta \in x$ and whenever $X \in x$ and $X \; f \; Y$, then $Y \in x$. Thus, by induction, if $\Delta f^n X$, then $X \in x$. So $\mathrm{fix}(f) \subseteq x$.

Finally, if $\mathrm{fax} : (D \to D) \to D$ were any other operator satisfying (i) and (ii), we would prove at once that

$$\mathrm{fix}(f) \subseteq \mathrm{fax}(f) \quad \text{and}$$

$$\mathrm{fax}(f) \subseteq \mathrm{fix}(f).$$

That is to say, the two operators are identical. □

The reader may have noticed that we used recursion in the proof of 4.1 (we had to define f^n for all $n \in \mathbf{N}$). But 4.1 and 4.2 can be used to justify definitions by recursion on a large number of domains — definitions where the process of iteration is far from being as straightforward. In discussing this point, let us start with some basic examples.

The fix combinator and its approximability / leastness / iterate-supremum laws are with the fix combinator peer.

Theorem (`theorem_42`). The fix combinator sends each function-space element to a fixed point of the recovered map, is least among postfixed points, and equals the directed supremum of the iterate elements from bottom.

Proof. Invoke the fixed-point law, the leastness law, and the directed-supremum law for the fix combinator. ■

4.5.6 Number domain

The flat neighbourhood system of natural numbers, with successor, predecessor, and zero-test as approximable maps.

Definition (`memN`). A subset of the naturals is a neighbourhood precisely when it is the universe or a singleton.

Proof. By definition. ■

Theorem (`memN_singleton`). Every singleton is a neighbourhood.

Proof. By definition. ■

Theorem (`memN_univ`). The universe is a neighbourhood.

Proof. By definition. ■

Theorem (`nestedOrDisjoint`). Any two neighbourhoods are nested or disjoint.

Proof. Case on the neighbourhood predicates: universals nest; a singleton nests in the universe; distinct singletons are disjoint. ■

Definition (`N`). The number domain is the neighbourhood system on the naturals generated by that nested-or-disjoint predicate with universe as master.

Proof. Assemble the nested-or-disjoint instance. ■

Theorem (`N_mem`). Membership in the number domain is the neighbourhood predicate.

Proof. By definition. ■

Theorem (`N_master`). The master neighbourhood is the universe.

Proof. By definition. ■

Definition (`T`). The two-token domain of truth values is the ambient truth domain.

Proof. By definition. ■

Definition (`natElem`). The numeral of a natural is the principal ideal of its singleton.

Proof. By definition. ■

Definition (`predVal`). The predecessor value sends zero to bottom and a successor numeral to the preceding numeral.

Proof. By recursion on the natural. ■

Theorem (`singleton_nat_inj`). Equal singletons determine equal naturals.

Proof. Membership of the left witness in the right singleton. ■

Theorem (`univ_ne_singleton`). The universe is not a singleton.

Proof. The successor of the singleton's element lies in the universe but not in the singleton. ■

Theorem (`singleton_ne_univ`). A singleton is not the universe.

Proof. Symmetry of the previous inequality. ■

Definition (`constLiftN`). A value assignment on naturals lifts to an approximable map from the number domain by relating the universe to the target master and each singleton to neighbourhoods of the assigned value.

Proof. Domain and codomain membership unpack the two clauses; the masters relate via the universe clause; right intersection and monotonicity case on those clauses using the singleton–universe inequalities. ■

Definition (`predMap`). Predecessor is the constant lift of the predecessor value.

Proof. By definition. ■

Definition (`succMap`). Successor is the constant lift of the successor-numeral assignment.

Proof. By definition. ■

Definition (`zeroElt`). Zero as an ideal element is the numeral of zero.

Proof. By definition. ■

Definition (`zeroVal`). The zero-test value sends zero to true and positive naturals to false.

Proof. By recursion on the natural. ■

Definition (`zeroMap`). The zero-test map is the constant lift of the zero-test value into the truth domain.

Proof. By definition. ■

Theorem (`N_bot_mem`). The bottom element of the number domain contains precisely the universe.

Proof. Invoke the general bottom-membership law. ■

Theorem (`constLiftN_bot`). A constant lift sends bottom to the target bottom.

Proof. Compare membership: a witnessing neighbourhood of bottom must be the universe, which forces the target master; conversely the target bottom is witnessed by the universe clause. ■

Theorem (`mem_natElem_iff`). A neighbourhood belongs to a numeral precisely when it is the universe or that numeral's singleton.

Proof. Unpack principal membership and the neighbourhood predicate. ■

Theorem (`constLiftN_natElem`). A constant lift evaluates at a numeral to the assigned value.

Proof. Compare membership using the numeral-membership characterisation and the singleton clause of the lift. ■

Theorem (`predMap_bot`). Predecessor sends bottom to bottom.

Proof. Invoke the constant-lift bottom law. ■

Theorem (`predMap_natElem_succ`). Predecessor of a successor numeral is the preceding numeral.

Proof. Invoke the constant-lift evaluation law. ■

Theorem (`predMap_natElem_zero`). Predecessor of the zero numeral is bottom.

Proof. Invoke the constant-lift evaluation law. ■

Theorem (`succMap_bot`). Successor sends bottom to bottom.

Proof. Invoke the constant-lift bottom law. ■

Theorem (`succMap_natElem`). Successor of a numeral is the next numeral.

Proof. Invoke the constant-lift evaluation law. ■

Theorem (`predMap_succMap_natElem`). Predecessor after successor recovers a numeral.

Proof. Compose the successor and predecessor evaluation laws. ■

Theorem (`zeroMap_bot`). The zero-test sends bottom to the truth-domain bottom.

Proof. Invoke the constant-lift bottom law. ■

Theorem (`zeroMap_natElem_succ`). The zero-test of a positive numeral is false.

Proof. Invoke the constant-lift evaluation law. ■

Theorem (`zeroMap_natElem_zero`). The zero-test of the zero numeral is true.

Proof. Invoke the constant-lift evaluation law. ■

4.5.7 Example 4.3 — partial functions on integers

EXAMPLE 4.3. The infinite generalization of our original example 1.2 is the system

$$N = \{\{n\} \mid n \in \mathbf{N}\} \cup \{\mathbf{N}\}.$$

The total elements are clearly in a one-one correspondence with the integers in $\mathbf{N}$. We can apply the construction of Exercise 3.16 to obtain a domain

$$F = N^{\infty}.$$

So we already know quite a bit about this domain — but it has a much more familiar presentation.

Let Φ be the set of all *finite partial functions* $\varphi \subseteq \mathbf{N} \times \mathbf{N}$ (that is, finite sets of ordered pairs of integers where, if $(n, m) \in \varphi$ and $(n, m') \in \varphi$, then $m = m'$). Define

$$\uparrow \varphi = \{\psi \in \Phi \mid \varphi \subseteq \psi\}.$$

Consider the neighbourhood system

$$F' = \{\uparrow \varphi \mid \varphi \in \Phi\}.$$

It is an easy exercise to show that F and F' are isomorphic and that the elements of these domains correspond exactly to the (possibly infinite) *partial functions* $\pi \subseteq \mathbf{N} \times \mathbf{N}$. Moreover, the *total* elements just correspond to the *total* functions $\tau : \mathbf{N} \to \mathbf{N}$ ("function" in the ordinary, set-theoretical sense of the word).

Another easy exercise is to show that the domains

$$F \text{ and } (\mathbf{N} \to \mathbf{N})$$

by our definitions are *NOT* isomorphic; though the two domains are closely related. We can define a mapping

$$\mathrm{val} : F \times N \to N$$

by the relationship

$$\uparrow \phi \cup \{n\} \text{ val } \{m\} \quad \text{iff} \quad (n, m) \in \phi.$$

(Of course val has to relate other neighbourhoods such as:

$$\uparrow \phi \cup N \text{ val } N,$$

but these are all.) It is then simple to prove that if $\pi \in |F|$ is regarded as a partial function $\pi : N \to N$ and if for $n \in N$ we define $\hat{n} \in |N|$ by

$$\hat{n} = \{\{n\}, N\},$$

then we have

$$\mathrm{val}(\pi, \hat{n}) = \widehat{\pi(n)}, \text{ if } \pi \text{ is defined at } n;$$

$$= \{N\}, \text{ otherwise.}$$

(Remember that $\{N\} \in |N|$ is the "undefined" element.) This means that

$$\mathrm{curry}(\mathrm{val}) : F \to (N \to N)$$

is a one-one function on elements. (The rather slight trouble with $(N \to N)$ is that it has *more* elements than F.)

So much for the construction of F, we now wish to consider mappings

$$f : F \to F$$

and their uses. Consider the possibility

$$f(\pi)(n) = 0, \qquad \text{if } n = 0;$$

$$= \pi(n-1) + n - 1, \text{ if } n > 0.$$

If π were a total function, then $f(\pi)$ would be total. But if π is partial, and if it is, say, undefined at k, then $f(\pi)$ becomes undefined at $k+1$. Note that $f(\pi)$ is always defined at 0. Note, too, that f is an approximable mapping because it is completely determined by what it does to finite (partial) functions. Indeed,

$$f(\pi) = \bigcup\{f(\phi) \mid \phi \subseteq \pi\},$$

where ϕ ranges over Φ.

Well, we have proved that every approximable map of a domain into itself has a (*least*) fixed point. What is the least fixed point of this f? Suppose $\sigma = f(\sigma)$. Then $\sigma(0) = 0$, and

$$\sigma(n+1) = f(\sigma)(n+1)$$

$$= \sigma(n) + n.$$

By induction, then

$$\sigma(n) = \sum_{i<n} i$$

and σ is a total function. (Therefore, f has a *unique* fixed point.)

Actually, we can make the procedure more systematic by defining as fixed points elements of $(N \to N)$ rather than F. In the first place we have $\hat{0} \in |N|$, and from now on we will not distinguish between n and $\hat{n}$. Next we have two mappings:

$$\text{succ}, \text{pred} : N \to N$$

where, as approximable mappings we have

$$X \text{ succ } Y \text{ iff } \exists n \in N.\ n \in X \text{ and } n+1 \in Y,$$

$$X \text{ pred } Y \text{ iff } \exists n \in N.\ n+1 \in X \text{ and } n \in Y,$$

for all $X, Y \in N$. This is *correct*, but what we mean in more understandable terms is:

$$\text{succ}(n) = n + 1;$$

$$\text{pred}(n) = n - 1, \text{ if } n > 0;$$

$$= \perp, \text{ if } n = 0.$$

Here, n has been identified with $\hat{n} \in |N|$ and $\perp = \{N\} \in |N|$. Moreover, we have a mapping

$$\text{zero} : N \to T$$

which is such that

$$\text{zero}(n) = \text{true, if } n = 0;$$

$$= \text{false, if } n > 0.$$

The *structured domain*

$$\langle N, 0, \text{succ}, \text{pred}, \text{zero} \rangle$$

can be called "THE domain of integers" for our present theory. We shall meet many other structured domains in the sequel.

Now the iterated summation function σ can be completely characterized — as a map $\sigma : N \to N$ rather than as an element $\sigma \in |F|$ — by the following equation:

$$\sigma(n) = \text{cond}(\text{zero}(n),\ 0,\ \sigma(\text{pred}(n)) + \text{pred}(n)).$$

The only problem is that we have not defined $+ : N \times N \to N$. (A direct definition is left to the reader; general remarks are given later.) But $+$ could be any function of two variables in order to make the point about the form of the definition of σ. Remember

$$\text{cond} : T \times N \times N \to N,$$

as defined in Exercise 3.26. We do not put cond in as part of the structure of N because (as should be clear from 3.26) it is part of the structure of T.

The above equation for σ is properly called a *functional equation*; it will be written as a fixed-point equation in Lecture V when we have the notation for the λ-calculus. □

The flat number system and its successor / predecessor / zero-test maps are with the number domain peer.

Theorem (`example_43`). On numerals, successor advances the index, predecessor recovers the predecessor or bottom at zero, both maps send bottom to bottom, the zero-test distinguishes zero from positive numerals and sends bottom to the truth-domain bottom, and predecessor after successor is the identity on numerals.

Proof. Invoke the corresponding evaluation and bottom laws for successor, predecessor, and the zero-test. ■

4.5.8 Sequence domain

The neighbourhood system of finite or infinite binary sequences, with bit-cons maps and the alternating fixed-point element.

Definition (`memC`). A set of strings is a sequence neighbourhood precisely when it is a cone or a singleton.

Proof. By definition. ■

Theorem (`memC_cone`). Every cone is a sequence neighbourhood.

Proof. By definition. ■

Theorem (`memC_singleton`). Every singleton is a sequence neighbourhood.

Proof. By definition. ■

Theorem (`prepend_mono`). Prepending a fixed string preserves inclusion of sets of strings.

Proof. Unpack membership in the prepended set and apply the given inclusion to the suffix. ■

Theorem (`prepend_singleton`). Prepending a string to a singleton yields the singleton of the concatenated string.

Proof. Compare membership in both directions. ■

Theorem (`singleton_subset_cone`). A singleton of a string lies in a cone precisely when the cone's prefix is a prefix of that string.

Proof. Unpack singleton inclusion and cone membership. ■

Theorem (`singleton_cone_nd`). A singleton and a cone are nested or disjoint: either the singleton lies in the cone, or the cone lies in the singleton, or their intersection is empty.

Proof. Case on whether the cone prefix is a prefix of the singleton's string; otherwise no common element can exist. ■

Theorem (`nestedOrDisjoint`). Any two sequence neighbourhoods are nested or disjoint.

Proof. Case on cones versus singletons, invoking cone trichotomy or the singleton–cone law, and for two singletons either they coincide or they are disjoint. ■

Definition (`C`). The sequence domain is the neighbourhood system on strings generated by that nested-or-disjoint predicate with the universe as master.

Proof. Assemble the nested-or-disjoint instance with the empty-string cone as a neighbourhood. ■

Theorem (`C_mem`). Membership in the sequence domain is the sequence-neighbourhood predicate.

Proof. By definition. ■

Theorem (`C_master`). The master neighbourhood is the universe of strings.

Proof. By definition. ■

Theorem (`memC_prepend`). Prepending a fixed string to a sequence neighbourhood yields a sequence neighbourhood.

Proof. Case on cones versus singletons and use the prepend–cone and prepend–singleton identities. ■

Definition (`consMap`). Bit-cons for a boolean relates neighbourhoods when the bit-prepended domain neighbourhood is contained in the codomain neighbourhood.

Proof. Domain and codomain membership are the first two conjuncts; the masters relate via the empty cone; right intersection and monotonicity use prepend monotonicity and that prepending preserves neighbourhoods. ■

Definition (`altElt`). The alternating element is the least fixed point of false-cons after true-cons.

Proof. By definition. ■

Definition (`strBot`). The partial string element of a finite string is the principal ideal of its cone.

Proof. By definition. ■

Definition (`strElem`). The total string element of a finite string is the principal ideal of its singleton.

Proof. By definition. ■

Theorem (`altElt_eq`). False-cons of true-cons of the alternating element recovers the alternating element.

Proof. Invoke the least-fixed-point law for the composite and unpack composition of element maps. ■

Theorem (`consMap_strBot`). Bit-cons prepends the bit on partial string elements.

Proof. Compare membership: a witnessing neighbourhood of the source cone forces the bit-prepended cone into the target; conversely that cone witnesses the relation. ■

Theorem (`consMap_strElem`). Bit-cons prepends the bit on total string elements.

Proof. Compare membership as for partial strings, using the prepend–singleton identity. ■

Theorem (`prepend_subset_self`). The trivial assertion holds.

Proof. Immediate. ■

4.5.9 Example 4.4 — sequence domain

EXAMPLE 4.4. The domain C of finite or infinite binary sequences mentioned in Exercise 2.21 may be regarded as a generalization of N. This can be made plain by saying how we wish to regard C as a structured domain. To do this we should recall what C is as a neighbourhood system. In the first place

$$B = \{\sigma\Sigma^* \mid \sigma \in \Sigma^*\}$$

where $\Sigma = \{0, 1\}$. To form the system C we have

$$C = B \cup \{\{\sigma\} \mid \sigma \in \Sigma^*\}.$$

The total elements of B correspond to *infinite binary sequences*; while the total elements of C to *finite or infinite sequences*. To simplify notation let us write for $\sigma \in \Sigma^*$

$$\sigma = \uparrow \{\sigma\} \quad \text{(a total element);}$$

$$\sigma \perp = \uparrow \sigma\Sigma^* \quad \text{(a partial element).}$$

In other words we identify σ with the corresponding total element in $|C|$.

We wish now to think of C as a structured domain seen as a kind of generalization of N. The empty sequence Λ will play the rôle of $0 \in |N|$; the map succ has two different analogues for C, however. Just as for B we define for $x \in |C|$ and $\sigma \in \Sigma^*$:

$$\sigma x = \{Y \mid \sigma X \subseteq Y \text{ some } X \in x\},$$

where of course now X and Y range over C. It should be checked that $\sigma\tau$ has the right meaning whether we think of $\tau \in \Sigma^*$ or $\tau \in |C|$. The two "successor" mappings we are looking for are

$$x \mapsto 0x \quad \text{and} \quad x \mapsto 1x.$$

All the maps $x \mapsto \sigma x$ can be obtained as compositions of these iterated as many times as needed.

Here are two questions which we now should ask:

What plays the rôle of pred?

The mapping will be called **tail**, and it is characterized by:

$$\text{tail}(0x) = x,$$

$$\mathrm{tail}(1x) = x, \text{ and}$$

$$\mathrm{tail}(\Lambda) = \perp .$$

It is left to the reader to show that **tail** exists as an approximable mapping.

What plays the rôle of zero?

The answer is not unique, because in C there are several distinctions that have to be made; in fact we will define three maps:

$$\mathrm{empty}, \mathrm{zero}, \mathrm{one} : C \to T$$

where the three maps take on truth-values to distinguish various kinds of elements in $|C|$ as follows:

$$\begin{aligned}
\mathrm{empty}\,(\Lambda) &= \mathrm{true},\\
\mathrm{empty}\,(0x) &= \mathrm{false},\\
\mathrm{empty}\,(1x) &= \mathrm{false},\\
\mathrm{zero}\,(\Lambda) &= \mathrm{false}\\
\mathrm{zero}\,(0x) &= \mathrm{true}\\
\mathrm{zero}\,(1x) &= \mathrm{false}\\
\mathrm{one}\,(\Lambda) &= \mathrm{false}\\
\mathrm{one}\,(0x) &= \mathrm{false}\\
\mathrm{one}\,(1x) &= \mathrm{true}.
\end{aligned}$$

Again, it is an exercise to show these are approximable. The structured domain is therefore

$$\langle C, \Lambda, 0, 1, \mathrm{tail}, \mathrm{empty}, \mathrm{zero}, \mathrm{one}\rangle.$$

Note that we have changed the meaning of some of the symbols in passing from N to C. Note too that there is a confusion between 0 as an element and 0 as the map $x \mapsto 0x$. There are just too few symbols! In any case this is only an example and not a philosophy of life, so the reader can be expected not to suffer too much.

An example of a definition of an *element* of $|C|$ by a fixed-point equation is:

$$a = 0\,1\,a.$$

This equation has one and only one solution in $|C|$, the infinite sequence that alternates 0's and 1's. Note that a is also characterized by:

$$a = 0101a.$$

Another element is

$$b = 010\,b,$$

which is quite different from a.

An example of a *map* in $|C \to C|$ has the characterization

$$d(\Lambda) = \Lambda$$
$$d(0x) = 00d(x), \quad \text{and}$$
$$d(1x) = 11d(x).$$

We can write:

$$d(x) = \mathrm{cond}(\mathrm{empty}(x),\ \Lambda,\ \mathrm{cond}(\mathrm{zero}(x),\ 00d(\mathrm{tail}(x)),\ 11d(\mathrm{tail}(x)))).$$

As we shall see in due course, this can be regarded as a fixed-point definition of d.

An example of a map in $|C \times C \to C|$ was suggested in 2.21. We can write:

$$xy = \mathrm{cond}(\mathrm{empty}(x),\ y,\ \mathrm{cond}(\mathrm{zero}(x),\ 0(\mathrm{tail}(x)\,y),\ 1(\mathrm{tail}(x)\,y))).$$

It should be checked that this equation exactly characterizes the intended mapping. □

The examples we have given with N and C are examples of definitions of functions by *recursion*. The literal meaning of "recursion" is "running backwards", and a look at the equations for our examples will show that the functions are characterized by giving their values either *outright* (e.g. at 0 or at Λ) or at *earlier* arguments (e.g. at $\mathrm{pred}(x)$ or at $\mathrm{tail}(x)$). The reader should keep in mind that a recursive "definition" is not really a definition in the sense of *explicit definition* but rather is a characterization; a theorem has to be proved to show that such functions exist. Now we have a general definition of domain and a general theorem on fixed points and a general construction of function-space domain; THEREFORE, we know that there are solutions to our equations PROVIDED THAT the variables range over elements of a domain and that the other, given functions that appear in the equations are already known to be approximable (continuous). This proviso is very important, and we shall remark on it time after time.

But, as is well known, recursion also can be done over sets like $\mathbf{N}$, and we should examine now the connection between the familiar kind of recursion and what we are doing over domains. Of course, one simple connection is already provided by the way we regard $\mathbf{N}$ as a subset of N. But there are other useful connections that can be employed in a way that may seem more direct.

The sequence system with cons maps and the alternating fixed point are with the sequence domain peer.

Theorem (`example_44`). False-cons of true-cons of the alternating element recovers that element, and bit-cons prepends the bit on both partial and total string elements.

Proof. Invoke the alternating fixed-point law and the two bit-cons evaluation laws. ■

4.5.10 Definition 4.5 — Peano axioms

DEFINITION 4.5. A structured set $\langle \mathbf{N}, 0, {}^+ \rangle$, where $0 \in \mathbf{N}$ and ${}^+ : \mathbf{N} \to \mathbf{N}$ is a unary function, is said to be a *model for Peano's Axioms* if the following conditions are satisfied:

(i) $0 \neq n^+$, for all $n \in \mathbf{N}$;

(ii) $n^+ = m^+$ implies $n = m$, for all $n, m \in \mathbf{N}$;

(iii) whenever $x \subseteq \mathbf{N}$ and $0 \in x$ and $x^+ \subseteq x$, then $x = \mathbf{N}$.

Here $x^+ = \{n^+ \mid n \in x\}$. □

Clause (iii) is recognized as the principle of mathematical induction stated in terms of sets. We usually think of $\mathbf{N}$ as being "God given", and (i)–(iii) as known without question. Suppose God, however, decides to withdraw His set of integers and substitute another. We can ask: "Oh! Why did You take from us our beloved numbers? Why must we now live with these strange new beasts?" God will probably reply "Trust Me!" Perhaps we should in view of the theorem:

Definition (`PeanoModel`). A Peano model on a type carries a zero element and a successor operation such that zero is never a successor, successor is injective, and every set containing zero and closed under successor is the whole carrier.

Proof. By definition. ■

Definition (`PeanoModel.Graph`). The Peano graph of two models is the inductive relation generated by pairing the two zeros and closed under simultaneous succession.

Proof. By the inductive clauses. ■

Theorem (`PeanoModel.Graph.swap`). The Peano graph is symmetric: a related pair yields the swapped pair for the swapped models.

Proof. Induct on the graph derivation, swapping the base and step clauses. ■

Theorem (`PeanoModel.graph_succ_right`). If a successor on the left is related to an element on the right, that right element is the successor of a uniquely determined predecessor related to the left predecessor.

Proof. Case on the graph derivation: the base clause contradicts that zero is never a successor; the step clause and injectivity of successor recover the predecessor pair. ■

Theorem (`PeanoModel.graph_zero_right`). If the left zero is related to a right element, that element is the right zero.

Proof. Case on the graph derivation: the step clause would force zero to be a successor. ■

Theorem (`PeanoModel.exists_unique_right`). For each left element there is a unique right element related by the Peano graph.

Proof. Induct on the left model: uniqueness at zero uses the zero-right law; uniqueness at a successor uses the successor-right law and uniqueness at the predecessor. ■

Theorem (`PeanoModel.exists_unique_left`). For each right element there is a unique left element related by the Peano graph.

Proof. Apply uniqueness on the right to the swapped models and swap the witnessing pairs. ■

4.5.11 Theorem 4.6 — Peano models isomorphic

THEOREM 4.6. All models of Peano's Axioms are isomorphic.

Proof: There are several ways to give the proof, but, for the sake of illustration, an application of the fixed-point theorem is appropriate here. Let $\langle \mathbf{N}, 0, {}^{+} \rangle$ be one model, and let $\langle \mathbf{M}, \Box, {}^{\#} \rangle$ be another. Let $\mathbf{N} \times \mathbf{M}$ be the ordinary cartesian product of the two sets and let

$$P(\mathbf{N} \times \mathbf{M})$$

be the powerset (set of all subsets) of $\mathbf{N} \times \mathbf{N}$. As in Exercises 1.15 and 2.20, we regard this set of elements as a domain, whose finite elements are just the finite subsets of the given set $\mathbf{N} \times \mathbf{M}$. The following mapping on $u \subseteq \mathbf{N} \times \mathbf{M}$ is easily proved approximable:

$$u \mapsto \{(0, \Box)\} \cup \{(n^{+}, m^{\#}) \mid (n, m) \in u\}.$$

(This assertion should be checked as an exercise.) We thus let r be the (least) fixed point:

$$r = \{(0, \Box)\} \cup \{(n^{+}, m^{\#}) \mid (n, m) \in r\}.$$

This $r \subseteq \mathbf{N} \times \mathbf{M}$ as a binary relation will turn out to be a one-one correspondence giving the required isomorphism.

First of all we see by construction that

(i) $0\ r\ \square$;

(ii) $n\ r\ m$ implies $n^+\ r\ m^\#$.

So, if r proves to be a one-one correspondence, it will then be the desired isomorphism. Now, the two sets shown in the equation

$$\{(0, \square)\} \cap \{(n^+, m^\#) \mid (n, m) \in r\} = \emptyset$$

are disjoint by virtue of axiom 4.5(i). Therefore, 0 in $\mathbf{N}$ corresponds by r to one and only one element of $\mathbf{M}$, namely the element $\square$. Let $x \subseteq \mathbf{N}$ be the set of all elements of $\mathbf{N}$ corresponding by r to a unique element of $\mathbf{M}$. We have just shown $0 \in x$. Suppose $n \in x$, and let $m \in \mathbf{M}$ be the unique element with $n\ r\ m$. Now $n^+\ r\ m^\#$ holds, so n^+ corresponds to at least one element of $\mathbf{M}$. If $n^+\ r\ k$ also holds, then since $(n^+, k) \neq (0, \square)$, the fixed-point equation implies

$$n^+ = n_0^+ \quad \text{and} \quad k = m_0^\#$$

for some $(n_0, m_0) \in r$. By axiom 4.5(ii), $n = n_0$, and, by uniqueness (remember $n \in x$), $m = m_0$; thus, $m^\#$ is the unique correspondent for n^+. We have proved $n^+ \in x$. Therefore, $x^+ \subseteq x$; so by axiom 4.5(iii), $x = \mathbf{N}$ holds. Otherwise said, every element in $\mathbf{N}$ corresponds to a unique element of $\mathbf{M}$.

Note that the rôles of $\mathbf{N}$ and $\mathbf{M}$ are completely symmetric, *and* they satisfy the same axioms as structured sets. It follows, then, that every element of $\mathbf{M}$ corresponds to a unique element of $\mathbf{N}$. The proof that r is a one-one correspondence is now complete. $\square$

Theorem (`PeanoModel.peano_models_isomorphic`). Any two Peano models are isomorphic by an equivalence sending zero to zero and commuting with successor.

Proof. Build the equivalence from the unique Peano-graph partners on each side, using uniqueness to check the inverse laws, and the base and step clauses to check that zero and successor are preserved. ■

Theorem (`PeanoModel.theorem_46`). All models of Peano's axioms are isomorphic by a zero-and-successor-preserving equivalence.

Proof. Invoke the Peano-model isomorphism theorem. ■

4.5.12 Fixed point above a seed

Least fixed point of an endomap above a seed that lies below its image, obtained as the directed supremum of the iterates from that seed.

Definition (`ApproximableMap.iterFrom`). The n-fold iterate of an endomap from a seed is the n-fold application of its element map to that seed.

Proof. By definition. ■

Theorem (`ApproximableMap.iterFrom_zero`). The zero-fold iterate is the seed.

Proof. By definition. ■

Theorem (`ApproximableMap.iterFrom_succ`). The successor iterate applies the element map once more.

Proof. Unpack iteration at a successor. ■

Theorem (`ApproximableMap.iterFrom_step`). If the seed lies below its image, successive iterates are increasing.

Proof. Induct on the step index, using monotonicity of the element map. ■

Theorem (`ApproximableMap.iterFrom_mono`). If the seed lies below its image, iterates are monotone in the step index.

Proof. Induct along the inequality of indices, chaining the one-step increase. ■

Definition (`ApproximableMap.fixAbove`). The least fixed point above a seed below its image is the directed supremum of the iterates from that seed.

Proof. Directedness of the iterates follows from monotonicity in the step index. ■

Theorem (`ApproximableMap.fixAbove_isFixed`). The directed supremum of the iterates from such a seed is a fixed point of the endomap.

Proof. Compare both directions: applying the map sends each iterate to the next, hence into the supremum; each iterate lies below the image of the supremum by monotonicity of the map and of the iterates. ■

Theorem (`ApproximableMap.fixAbove_least`). Among postfixed points above the seed, that directed supremum is least.

Proof. Induct on the iterate index: the seed lies below the postfixed point, and the inductive step uses monotonicity of the map together with the postfix inequality. ■

Theorem (`ApproximableMap.le_fixAbove`). The seed lies below the directed supremum of its iterates.

Proof. The zero-fold iterate is the seed and lies below every directed supremum of the iterates. ■

4.5.13 Exercise 4.7 — fixed point above a seed

Formula 4.2(iii) shows how to find the *least* fixed point of $f : D \to D$. Suppose on the other hand that $a \in |D|$ is such that $a \subseteq f(a)$. Will there be a fixed point $x = f(x)$ with $a \subseteq x$?

(Hint: How do we know $\bigsqcup_{n=0}^{\infty} f^n(\bot) \in |D|$?)

The fixed point above a seed and its leastness laws are with the fixed point above a seed peer.

Theorem (`example_407`). If a seed lies below its image under an endomap, the directed supremum of the iterates from that seed is a fixed point, and it is least among postfixed points above the seed.

Proof. Invoke the fixed-point and leastness laws for the fixed point above a seed. ■

4.5.14 Iterate-chain supremum

Directed supremum of a monotone $\mathbb{N}$-indexed chain of elements, and the characterisation of the least fixed-point element as the supremum of the iterate elements from bottom.

Definition (`ApproximableMap.supChain`). The supremum of a monotone $\mathbb{N}$-indexed chain of elements is their directed supremum along the maximum-index directedness.

Proof. By definition. ■

Theorem (`ApproximableMap.iterElem_monotone`). The iterate elements of an endomap from bottom form a monotone sequence.

Proof. Invoke monotonicity of iterate elements in the step index. ■

Theorem (`ApproximableMap.iterElem_succ`). The successor iterate element is the image of the previous under the endomap.

Proof. Unpack the iterate-map composition at a successor and the element-map composition law. ■

Theorem (`ApproximableMap.iterElem_zero`). The zero-fold iterate element is bottom.

Proof. The zero iterate map is the identity, which sends bottom to bottom. ■

Theorem (`ApproximableMap.comp_self_iterElem`). The n-fold iterate element of an endomap composed with itself equals the $2n$-fold iterate element of the original map.

Proof. Induct on n, using the successor and zero laws for iterate elements together with composition of element maps. ■

Theorem (`ApproximableMap.mem_supChain`). A neighbourhood belongs to a chain supremum precisely when it belongs to some stage of the chain.

Proof. Invoke the membership law for directed suprema. ■

Theorem (`ApproximableMap.fixElement_eq_supChain`). The least fixed-point element is the chain supremum of the iterate elements from bottom.

Proof. Compare membership using the directed-supremum and least-fixed-point membership characterisations together with the iterate-element membership law. ■

4.5.15 Fixed-point induction

Fixed-point induction along iterate chains from bottom, and equality of commuting maps at the least fixed point.

Theorem (`ApproximableMap.fix_induction`). A property of elements that holds at bottom, is preserved by an endomap, and is closed under directed chain-suprema holds at the least fixed point of that map.

Proof. The iterate elements from bottom satisfy the property by induction on the step index; the least fixed point is their chain supremum, so the supremum hypothesis applies. ■

Theorem (`ApproximableMap.fix_induction_eq`). Two maps that agree at bottom and each commute with an endomap agree at that endomap's least fixed point.

Proof. Apply fixed-point induction to equality of the two element maps, using the commutation laws at the successor step and directed-supremum continuity for the chain-supremum step. ■

4.5.16 Exercise 4.8 — fixed-point induction

Suppose $f : D \to D$ and $S \subseteq |D|$ are such that

(i) $\bot \in S$;

(ii) $x \in S$ always implies $f(x) \in S$;

(iii) whenever $\{x_n\}_{n=0}^{\infty} \subseteq S$ and $x_n \sqsubseteq x_{n+1}$ for all n, then $\bigsqcup_{n=0}^{\infty} x_n \in S$.

Conclude that $\mathrm{fix}(f) \in S$. (This could be called the principle of *fixed-point induction*.) Apply the method to a set of the form

$$S = \{x \in |D| \mid a(x) = b(x)\},$$

where $a, b : D \to D$ are approximable, and where we know $a(\bot) = b(\bot)$, and $f \circ a = a \circ f$ and $f \circ b = b \circ f$.

The induction principle and its equality application are with the fixed-point induction peer.

Theorem (`example_408`). Fixed-point induction holds: a property true at bottom, preserved by an endomap, and closed under monotone chain-suprema holds at the least fixed point; and two maps that agree at bottom and commute with the endomap agree at that least fixed point.

Proof. Invoke the fixed-point induction theorem and its equality corollary. ■

```

4.5.17 Psi operator

The approximable operator Ψ that evaluates a functional at a map by applying that map to the functional's value, and the characterisation of the fix combinator as Ψ's least fixed point.

Definition (`bigPsi`). The operator Ψ on functionals is the curry of evaluation composed with pairing the first projection against evaluation of function-space maps.

Proof. By definition. ■

Theorem (`bigPsi_apply`). Applying Ψ to a functional and then to a map yields the map applied to the functional at that map.

Proof. Unpack the curry, composition, pairing, projection, and evaluation laws. ■

Theorem (`toApproxMap_toFilter_fixMap`). The approximable map recovered from the filtered fix combinator is the fix combinator itself.

Proof. Invoke the function-space equivalence unit. ■

Theorem (`bigPsi_fix`). The filtered fix combinator is a fixed point of Ψ.

Proof. Compare recovered maps via the evaluation law for Ψ and the fixed-point law for the fix combinator. ■

Theorem (`bigPsi_least`). Among postfixed points of Ψ, the filtered fix combinator is least.

Proof. A postfix inequality for Ψ yields a postfix inequality at each map, so the least-fixed-point law for each map places the fix combinator below the functional. ■

Theorem (`fix_eq_fixElement_bigPsi`). The filtered fix combinator is the least fixed-point element of Ψ.

Proof. Combine leastness of the filtered fix combinator among postfixed points of Ψ with leastness of the least fixed-point element. ■

4.5.18 Exercise 4.9 — fix as a fixed point

Show that there is an approximable operator

$$\Psi : ((D \to D) \to D) \to ((D \to D) \to D)$$

such that for $\theta : (D \to D) \to D$ and $f : D \to D$ we have

$$\Psi(\theta)(f) = f(\theta(f)).$$

Prove further that $\mathrm{fix} : (D \to D) \to D$ is the *least* fixed point of Ψ.

The operator Ψ and its least-fixed-point characterisation of fix are with the Psi operator peer.

Theorem (`example_409`). The operator Ψ evaluates a functional at a map by applying that map to the functional's value; the filtered fix combinator is a fixed point of Ψ, least among postfixed points, and equals Ψ's least fixed-point element.

Proof. Invoke the evaluation, fixed-point, leastness, and least-fixed-point characterisation laws for Ψ. ■

4.5.19 Domain above an element

The neighbourhood system of neighbourhoods of a fixed element, with embedding, restriction, the induced endomap, and the inclusion into the ambient domain.

Definition (`ApproximableMap.relSystem`). The relative neighbourhood system of an element has the same master as the ambient system and neighbourhoods precisely those belonging to that element.

Proof. By definition. ■

Theorem (`ApproximableMap.relSystem_mem`). Membership in the relative system is membership in the element.

Proof. By definition. ■

Theorem (`ApproximableMap.relSystem_master`). The relative master is the ambient master.

Proof. By definition. ■

Definition (`ApproximableMap.embed`). Embedding a relative element into the ambient domain records ambient neighbourhoods that contain a relative neighbourhood of the element.

Proof. Intersection and upward closure unpack the ambient and relative element laws. ■

Theorem (`ApproximableMap.embed_le`). An embedded relative element lies below the seed element.

Proof. Upward-close a witnessing neighbourhood of the seed. ■

Theorem (`ApproximableMap.embed_mono`). Embedding is monotone.

Proof. Apply the relative inequality to the witnessing neighbourhood. ■

Theorem (`ApproximableMap.le_of_embed_le`). An inequality of embeddings recovers an inequality of relative elements.

Proof. Test membership by embedding a principal witness and unpacking. ■

Definition (`ApproximableMap.relMap`). An endomap that fixes a seed induces an endomap of the relative system by relating only neighbourhoods of that seed.

Proof. Codomain membership uses the fixed-point hypothesis; the remaining approximability laws unpack those of the ambient map. ■

Definition (`ApproximableMap.restrict`). Restricting an ambient element below the seed yields a relative element with the same neighbourhoods.

Proof. By definition. ■

Theorem (`ApproximableMap.embed_restrict`). Embedding the restriction of an element below the seed recovers that element.

Proof. Compare membership both ways. ■

Theorem (`ApproximableMap.restrict_embed`). Restricting an embedding recovers the relative element.

Proof. Compare membership both ways. ■

Definition (`ApproximableMap.relIso`). Relative elements are order-isomorphic to ambient elements below the seed via embed and restrict.

Proof. Assemble the mutual inverses and the embedding monotonicity laws. ■

Theorem (`ApproximableMap.fixElement_below_unique`). A fixed point below the least fixed-point element equals that least fixed point.

Proof. Leastness of the least fixed-point element yields the reverse inequality. ■

Theorem (`ApproximableMap.relMap_toElementMap_embed`). Embedding intertwines the relative endomap with the ambient endomap.

Proof. Compare membership of neighbourhoods under the two composite evaluations. ■

Theorem (`ApproximableMap.relMap_unique_fixed`). The unique fixed point of the relative endomap on the least fixed-point seed is the restricted least fixed-point element.

Proof. The embedded relative fixed point is an ambient fixed point below the least fixed point, hence equals it; transport back by restriction. ■

Definition (`ApproximableMap.inclMap`). Inclusion from the relative system to the ambient domain relates a relative neighbourhood to an ambient neighbourhood containing it.

Proof. Approximability unpacks ambient intersection and inclusion. ■

Theorem (`ApproximableMap.inclMap_toElementMap`). Inclusion evaluates as embedding.

Proof. Compare membership. ■

Theorem (`ApproximableMap.inclMap_bot`). Inclusion sends relative bottom to ambient bottom.

Proof. Unpack embedding of bottom. ■

Theorem (`ApproximableMap.inclMap_intertwine`). Inclusion intertwines the relative endomap with the ambient endomap.

Proof. Compose the inclusion-as-embedding law with the relative–ambient intertwining law. ■

4.5.20 Exercise 4.10 — domain above an element

Given a domain D and an element $a \in |D|$, construct a domain D_a where

$$|D_a| = \{x \in |D| \mid x \sqsubseteq a\}.$$

Show that if $f : D \to D$ is approximable, then f can be restricted to an approximable map $f' : D_{\mathrm{fix}(f)} \to D_{\mathrm{fix}(f)}$ where $f'(x) = f(x)$ for all $x \in |D_{\mathrm{fix}(f)}|$. How many fixed points does f' have in $|D_{\mathrm{fix}(f)}|$?

The relative domain, induced endomap, and inclusion are with the domain above an element peer.

Theorem (`example_410`). A fixed point below the least fixed-point element equals that least fixed point, and the relative endomap on the least fixed-point seed has a unique fixed point, namely the restricted least fixed-point element.

Proof. Invoke uniqueness of fixed points below the least fixed-point element and uniqueness of relative fixed points on that seed. ■

4.5.21 Uniform fix uniqueness

Uniform characterisation of the least fixed-point assignment across domains, with commuting-map and iterate lemmas used in the uniqueness argument.

Theorem (`fix_unique_of_uniform`). Any assignment of fixed points to endomaps that is natural under strict intertwining maps equals the least fixed-point element on every domain.

Proof. Apply the assignment on the relative system of the least fixed-point element, use uniqueness of the relative fixed point, and transport along inclusion. ■

Theorem (`ApproximableMap.iterElem_le_fixElement`). Every iterate element from bottom lies below the least fixed-point element.

Proof. Unpack least-fixed-point membership. ■

Theorem (`ApproximableMap.fixElement_uniform`). A strict intertwining map sends least fixed points to least fixed points.

Proof. Compare images of iterates and use leastness on both sides. ■

Theorem (`ApproximableMap.commuting_least_common_fixed`). Commuting endomaps have a least common fixed point.

Proof. Take the fixed point of one map above the least fixed point of the other, using the fixed-point-above-a-seed construction. ■

Theorem (`ApproximableMap.fixElement_eq_of_commuting_bot`). Commuting endomaps that agree at bottom have the same least fixed point.

Proof. Show each least fixed point is fixed by the other map via iterate shifting. ■

Theorem (`ApproximableMap.fixElement_iterTwice`). The least fixed point of a map equals that of the map composed with itself.

Proof. Compare iterate chains using the double-step identity for iterate elements. ■

4.5.22 Exercise 4.11 — characterizing the fix combinator

(Suggested by G. Plotkin). We can regard fix as assigning a fixed-point operator to each domain D. Show that fix is uniquely determined by the following general conditions on an assignment $D \rightsquigarrow F_D$:

(i) $F_D : (D \to D) \to D$;

(ii) $F_D(f) = f(F_D(f))$ for all $f : D \to D$;

(iii) whenever $f_0 : D_0 \to D_0$ and $f_1 : D_1 \to D_1$ are given and $h : D_0 \to D_1$ is such that $h(\bot) = \bot$ and $h \circ f_0 = f_1 \circ h$, then $h(F_{D_0}(f_0)) = F_{D_1}(f_1)$.

(Hint: Apply 4.7 to prove fix satisfies (iii). In the other direction use 4.10.)

The uniform uniqueness theorem and its supporting lemmas are with the uniform fix uniqueness peer.

Theorem (`example_411`). Any assignment of fixed points to endomaps that is natural under strict intertwining maps equals the least fixed-point element on every domain.

Proof. Invoke the uniform uniqueness theorem. ■

4.5.23 No greatest fixed point

The identity endomap on Example 1.2 has every element fixed but no greatest among those fixed points.

Definition (`noGreatestFixedDomain`). The neighbourhood system for Exercise 4.12 is the Example 1.2 token domain.

Proof. By definition. ■

Theorem (`one_ne_zero`). The one and zero tokens are distinct.

Proof. Distinctness of numeric tokens. ■

Theorem (`one_ne_master`). The one token is not the master token.

Proof. Membership in the one token neighbourhood refutes zero lying in it. ■

Theorem (`zero_ne_master`). The zero token is not the master token.

Proof. Membership in the zero token neighbourhood refutes one lying in it. ■

Theorem (`elemOne_not_le_elemZero`). The one element does not lie below the zero element.

Proof. Any way-one below relation at the one token forces incompatibility with master or zero classification. ■

Theorem (`elemZero_not_le_elemOne`). The zero element does not lie below the one element.

Proof. Any way-zero below relation at the zero token forces incompatibility with master or one classification. ■

Theorem (`idMap_fixed`). Every element is fixed by the identity approximable map.

Proof. The identity element map fixes every element. ■

Theorem (`no_greatest_fixedPoint`). No element is a greatest common bound of all fixed points of the identity map.

Proof. Any purported greatest fixed point would have to dominate both the zero and one elements; token classification of elements rules out each of the three cases. ■

4.5.24 Exercise 4.12 — no greatest fixed point

Need an approximable $f : D \to D$ have a maximum fixed point? Give an example where there are many fixed points.

The counterexample and non-existence of a greatest fixed point are with the No greatest fixed point peer.

Theorem (`example_412`). On Example 1.2, the identity map fixes every element, yet no element is a greatest fixed point.

Proof. Invoke the universal fixed-point law for the identity and the non-existence of a greatest common fixed point. ■

Exercise_4_12.lean

4.5.25 Monotone fixed-point operator

Monotone endomaps admit a least fixed point as the infimum of pre-fixed points; primitive recursion on $\mathbb{N}$ is unique; chain unions lie below upper bounds.

Definition (`NeighborhoodSystem.preFix`). For an endomap on elements, the pre-fixed points are those with image below the point.

Proof. By definition. ■

Theorem (`NeighborhoodSystem.mem_preFix`). Membership in the pre-fixed set is equivalent to the pre-fix inequality.

Proof. By definition. ■

Definition (`NeighborhoodSystem.monoFix`). Given a pre-fixed seed, the monotone fixed point is the infimum of all pre-fixed points.

Proof. Nonempty pre-fixed set supplies the seed for the infimum. ■

Theorem (`NeighborhoodSystem.exists_unique_nat_rec`). For any set with seed and unary operation, there is a unique $\mathbb{N}$-indexed sequence starting at the seed and stepping by the operation.

Proof. Recursion defines a witness; extensionality on $\mathbb{N}$ proves uniqueness. ■

Theorem (`NeighborhoodSystem.monoFix_le_preFix`). The monotone fixed point lies below every pre-fixed point.

Proof. Infimum comparison against the pre-fixed set. ■

Theorem (`NeighborhoodSystem.monoFix_le`). The monotone fixed point lies below the chosen seed pre-fixed point.

Proof. Specialise the pre-fixed bound with the seed. ■

Theorem (`NeighborhoodSystem.monoFix_least`). The monotone fixed point is below every exact fixed point.

Proof. A fixed point is pre-fixed; apply the pre-fixed bound. ■

Theorem (`NeighborhoodSystem.monoFix_preFix`). Under monotonicity, the image of the monotone fixed point is again pre-fixed.

Proof. Every pre-fixed point dominates the fixed point; monotonicity transports the inequality into the pre-fixed set, which the fixed point infimum bounds from below. ■

Theorem (`NeighborhoodSystem.monoFix_isFixed`). Under monotonicity, the monotone fixed point from a pre-fixed seed is a fixed point.

Proof. Image below and above the fixed point from pre-fix lemmas, then antisymmetry. ■

Theorem (`NeighborhoodSystem.nat_iterate_unique`). The successor iteration starting at zero that adds one each step equals the identity on $\mathbb{N}$.

Proof. Induction on the index using the step and base hypotheses. ■

Theorem (`NeighborhoodSystem.chainUnion_le`). The chain union of a nonempty chain lies below any upper bound of its members.

Proof. Each member of the union comes from some chain element below the bound. ■

4.5.26 Exercise 4.13 — avoiding the natural numbers

The proof of 4.1 uses the integers, whereas the proof of 4.6 uses 4.1. There is a hint of circularity here! It can be eliminated by the following steps:

(1) If a domain D has an element a where, for $f : D \to D$, the relation $f(a) \sqsubseteq a$ holds, then the least fixed point can be defined by

$$\mathrm{fix}(f) = \bigcap \{x \in |D| \mid f(x) \sqsubseteq x\}.$$

Note that $\mathrm{fix}(f) \sqsubseteq a$. (Hint: Remark that by 1.17 the formula gives a well-defined element. Call the element b. Prove that $f(b) \sqsubseteq b$ by showing that $f(b) \sqsubseteq x$ whenever $f(x) \sqsubseteq x$. Then note that $f(f(b)) \sqsubseteq f(b)$ so that $b \sqsubseteq f(b)$ also. Conclude $b = \mathrm{fix}(f)$ as least fixed point.)

(2) Remark that this proof uses only the monotonicity property of $f : |D| \to |D|$. Remark, too, that (1) can always be applied to power-set domains PA for any set A.

(3) Review the proof of 4.6 and establish by a fixed-point method that for any structured set $\langle Z, z, \cdot \rangle$ there is a unique function $s : \mathbf{N} \to Z$ such that

(i) $s(0) = z$;

(ii) $s(n^+) = s(n)^{\cdot}$, for $n \in \mathbf{N}$.

(4) Employ (3) for the proof of 4.1 by identifying $\langle \mathbf{N}, 0, {}^+ \rangle$.

The monotone intersection fixed point, primitive recursion, and chain-union bound are with the Monotone fixed-point operator peer.

Theorem (`example_413`). A monotone endomap's infimum-of-pre-fixed-points is a fixed point; primitive recursion is unique; that fixed point is least among exact fixed points; and the standard $\mathbb{N}$ successor walk from zero is the identity.

Proof. Invoke the fixed-point, uniqueness, leastness, and standard iteration laws from the monotone fixed-point operator. ■

4.5.27 Greatest powerset fixed point

Least and greatest fixed points of monotone set operators as intersections of pre-fixed points and unions of post-fixed points.

Definition (`gfpSet`). The greatest fixed-point set of a power-set endomap is the union of all post-fixed sets.

Proof. By definition. ■

Definition (`lfpSet`). The least fixed-point set of a power-set endomap is the intersection of all pre-fixed sets.

Proof. By definition. ■

Theorem (`lfpSet_subset`). The least fixed-point set lies inside every pre-fixed set.

Proof. Immediate from the universal quantifier in the definition. ■

Theorem (`f_subset_lfpSet`). Under monotonicity, the image of the least fixed-point set lies inside it.

Proof. Any pre-fixed set absorbs its image via monotonicity, so membership in the least fixed-point set propagates. ■

Theorem (`lfpSet_isFixed`). Under monotonicity, the least fixed-point set is a fixed point.

Proof. Subset inclusions both ways from the two preceding lemmas. ■

Theorem (`lfpSet_least`). The least fixed-point set lies inside every exact fixed set.

Proof. A fixed set is pre-fixed. ■

Theorem (`subset_gfpSet`). Every post-fixed set lies inside the greatest fixed-point set.

Proof. Exhibit the post-fixed set as witness in the union. ■

Theorem (`gfpSet_greatest`). Every exact fixed set lies inside the greatest fixed-point set.

Proof. A fixed set is post-fixed. ■

Theorem (`gfpSet_subset_f`). Under monotonicity, the greatest fixed-point set lies inside its image.

Proof. Witness membership via a post-fixed set contained in its image. ■

Theorem (`gfpSet_isFixed`). Under monotonicity, the greatest fixed-point set is a fixed point.

Proof. Subset inclusions both ways using post-fixed absorption and monotonicity. ■

4.5.29 Maximal fixed points

Zorn's lemma on post-fixed points yields maximal fixed points; least fixed points follow from the monotone intersection operator; an infimum of fixed points is mapped below itself.

Theorem (`NeighborhoodSystem.exists_maximal_fixedPoint`). Every monotone endomap has a fixed point maximal among fixed points that lie above it.

Proof. Zorn on the set of post-fixed points, using chain unions for upper bounds and monotonicity to close under f. ■

Theorem (`NeighborhoodSystem.exists_least_fixedPoint`). Every monotone endomap has a least fixed point.

Proof. Build the monotone intersection fixed point from a maximal fixed point seed. ■

Theorem (`NeighborhoodSystem.f_sInf_le`). Under monotonicity, if every member of a nonempty fixed-point set is exactly fixed, then the image of their infimum lies below the infimum.

Proof. Compare the image to each member via monotonicity and the fixed-point identities. ■

4.5.30 Exercise 4.15 — maximal fixed points

(For set theorists.) Let $f : |D| \to |D|$ be a monotone function on (the elements of) a domain. Show that f has a *maximal* fixed point (i.e. a fixed point that cannot be extended to a larger fixed point). (Hint: By Zorn's Lemma consider a maximal chain

$$C \subseteq \{x \in |D| \mid x \sqsubseteq f(x)\},$$

and use 2.11 to remark that $\bigsqcup C \in |D|$.) Now argue that f has a least fixed point.

Maximal and least fixed points for monotone endomaps, and the fixed-point inequality below an infimum of fixed points, are with the Maximal fixed points peer.

Theorem (`example_415`). Every monotone endomap has a least fixed point and a maximal fixed point that cannot be extended upward among fixed points.

Proof. Invoke the least and maximal existence laws from the maximal fixed-points peer. ■

4.5.31 Optimal fixed point

The optimal fixed point over a nonempty set of exact fixed points is the monotone least fixed point above the infimum fixed-point bound.

Definition (`NeighborhoodSystem.optimalFix`). Given a nonempty family of exact fixed points, the optimal fixed point is the monotone fixed point built from the infimum fixed-point inequality.

Proof. Well-defined from the seed inequality supplied for the infimum. ■

Theorem (`NeighborhoodSystem.optimalFix_isFixed`). The optimal fixed point is an exact fixed point.

Proof. Apply the monotone fixed-point fixed-point law. ■

Theorem (`NeighborhoodSystem.optimalFix_le_sInf`). The optimal fixed point lies below the infimum of the given fixed-point set.

Proof. The monotone fixed point lies below its seed. ■

Theorem (`NeighborhoodSystem.optimalFix_le`). The optimal fixed point lies below every member of the fixed-point set.

Proof. Transitivity through the infimum bound. ■

Theorem (`NeighborhoodSystem.optimalFix_consistent`). The optimal fixed point shares an upper bound with every member of the fixed-point set.

Proof. Each member bounds the optimal point from above. ■

4.5.32 Exercise 4.16 — optimal fixed point

(For fixed-point nuts). Show that a monotone function as in 4.15 has an "optimal" fixed point in the sense that it is the greatest fixed point below all the maximal fixed points and at the same time it is the largest fixed point consistent with all other fixed points. *Consistency* for sets of elements means having a common upper bound. (Hint: Follow these steps:

(1) Show that any non-empty set S of fixed points has a largest fixed point below by using the formula

$$f(\bigcap S) \sqsubseteq \bigcap S$$

and finding the least fixed point over $\bigcap S$.

(2) Letting a be the fixed point of (1) constructed from the set of maximal fixed points, remark that a is consistent with any other fixed point $x = f(x)$, since x can be extended to a maximal one. Suppose b is consistent with all fixed points, then $b \sqsubseteq y$ if y is maximal. (Why?).)

The infimum-of-fixed-points inequality and the optimal fixed point below every member of a fixed-point set are with the Optimal fixed point peer.

Theorem (`example_416`). For a nonempty set of fixed points of a monotone endomap, the image of the infimum lies below the infimum; the optimal fixed point is consistent with each member and lies below each.

Proof. Invoke the infimum fixed-point bound and the optimal fixed-point consistency and comparison laws. ■

4.5.33 Generated submonoid

The set operator $F\,a\,b\,x = \{1\} \cup \{a, b\} \cup x \cdot x$ on a monoid's power set is monotone; its least fixed point is the submonoid generated by $\{a, b\}$, and fixed points need not be unique.

Definition (`F`). The generated-submonoid operator unions the unit, $\{a, b\}$, and the set product $x \cdot x$.

Proof. By definition. ■

Theorem (`base_subset_F`). The unit and generators sit inside the operator image.

Proof. Left-hand inclusion of the union. ■

Theorem (`one_mem_F`). The unit lies in the operator image.

Proof. Via the base inclusion. ■

Theorem (`self_mul_subset_F`). The set square $x \cdot x$ lies inside the operator image.

Proof. Right-hand inclusion of the union. ■

Definition (`preFixSubmonoid`). A pre-fixed carrier yields a submonoid structure.

Proof. Closure under unit and multiplication from pre-fixed absorption. ■

Theorem (`F_monotone`). The operator is monotone on subsets.

Proof. Union and pointwise product respect inclusion. ■

Theorem (`F_one_one_singleton`). On $\mathbb{N}$, $F\,1\,1$ fixes the singleton $\{1\}$.

Proof. Evaluate the union and singleton product. ■

Theorem (`F_univ`). On any monoid, $F\,a\,b$ fixes the full set.

Proof. Every element lies in $x \cdot x$ when x is universal. ■

Theorem (`a_mem_F`). Generator a lies in the operator image.

Proof. Membership in the middle union piece. ■

Theorem (`b_mem_F`). Generator b lies in the operator image.

Proof. Membership in the middle union piece. ■

Theorem (`fixedPoint_not_unique`). Distinct fixed sets $\{1\}$ and $\mathbb{N}$ both satisfy $F\,1\,1\,x = x$ on $\mathbb{N}$.

Proof. Direct evaluation and separation at 2. ■

Theorem (`leastSolution_eq`). The least fixed-point set is fixed by $F\,a\,b$.

Proof. Apply the least fixed-point identity under monotonicity. ■

Theorem (`lfpSet_eq_closure`). The least fixed set equals the submonoid closure of $\{a, b\}$.

Proof. Closure absorbs the operator; the least fixed set contains the generators and hence the closure. ■

4.5.34 Exercise 4.17 — generated submonoid

(For algebraists). Suppose $\langle S, 1, \cdot \rangle$ is a semi-group with unit (sometimes called a monoid). Remark that PS is a domain. For $a, b \in S$, what is the least $x \in PS$ such that

$$x = \{1\} \cup \{a, b\} \cup x \cdot x,$$

where in general for $x, y \subseteq S$

$$x \cdot y = \{t \cdot u \mid t \in x \text{ and } u \in y\}?$$

Need the fixed point be unique?

The powerset operator, non-uniqueness of fixed points, and identification of the least solution with the submonoid generated by $\{a, b\}$ are with the Generated submonoid peer.

Theorem (`example_417`). On $\mathbb{N}$, the operator $F\,1\,1$ has distinct fixed points $\{1\}$ and $\mathbb{N}$; for any monoid, the least fixed set of $F\,a\,b$ equals the submonoid closure of $\{a, b\}$.

Proof. Exhibit the two fixed points on $\mathbb{N}$, then invoke the closure identification for general a, b. ■

```

4.5.35 Number-domain checks

Elements of the number neighbourhood domain are bottom or principal numerals; numerals and the successor approximable map are injective on indices; zero is distinct from successors.

Theorem (`singleton_inter_eq_empty`). Distinct singleton neighbourhood sets have empty intersection.

Proof. Extensionality on indices. ■

Theorem (`natElem_injective`). Equal numerals determine equal natural numbers.

Proof. Read membership in one numeral's singleton neighbourhood. ■

Theorem (`natElem_zero_ne_succ`). Zero and any positive numeral are unequal.

Proof. Transfer injectivity through successor indices. ■

Theorem (`not_N_mem_empty`). The empty set is not a valid neighbourhood.

Proof. Cases on the membership predicate. ■

Theorem (`element_classification`). Every element is bottom or a numeral.

Proof. Case on presence of a singleton neighbourhood; otherwise master and bot axioms force bottom. ■

Theorem (`succMap_injective`). Equal successor images imply equal indices.

Proof. Compare numerals after unfolding successor on numerals. ■

Theorem (`zero_ne_succMap`). Zero is not the successor image of a numeral.

Proof. Reduce to the zero-versus-successor numeral distinction. ■
