Keywords: Lean 4; formal verification; domain theory; continuous lattices; neighbourhood systems; information systems; Scott topology

Abstract

This document is a machine-checked Lean 4 formalization of Dana Scott's papers on domain theory: continuous lattices (1972), datatypes as lattices (1976), neighbourhood systems (1980), and information systems (1982), together with bridge theorems relating the lattice, neighbourhood, and information systems presentations.

Contents

1 Continuous Lattices (1972) 14

1.1 Introduction . . . 15
1.2 Injective spaces . . . 16
1.2.1 Definition 1.1: Injective Space . . . 17
1.2.2 Proposition 1.2 . . . 19
1.2.3 Proposition 1.3 . . . 19
1.2.4 Powers of $\mathbb{O}$ are injective . . . 20
1.2.5 Proposition 1.4 . . . 20
1.2.6 Proposition 1.5 . . . 21
1.2.7 RetractSubspace . . . 22
1.2.8 Corollary 1.6 . . . 22
1.2.9 Corollary 1.7 . . . 23
1.2.10 Absolute retracts . . . 24
1.3 Continuous lattices . . . 24
1.3.1 Specialization order . . . 26
1.3.2 Way-below relation . . . 33
1.3.3 Proposition 2.2 . . . 37
1.3.4 Definition 2.3 . . . 39
1.3.5 Proposition 2.4 . . . 40
1.3.6 Limits and convergence . . . 41
1.3.7 Scott maps . . . 42
1.3.8 Proposition 2.8 . . . 51
1.3.9 Proposition 2.9 . . . 53
1.3.10 Proposition 2.10 . . . 53
1.3.11 Proposition 2.11 . . . 53
1.3.12 Theorem 2.12 . . . 53
1.3.13 Proof of 2.9 . . . 53
1.3.14 Proof of 2.10 . . . 56
1.3.15 Proof of 2.11 . . . 60
1.3.16 Proof of 2.12 . . . 71
1.3.17 After Theorem 2.12 . . . 86
1.4 Function spaces . . . 87
1.4.1 Definition 3.1: Function space . . . 87
1.4.2 Proposition 3.2 . . . 96
1.4.3 Theorem 3.3 . . . 97
1.4.4 Corollary 3.4 . . . 152
1.4.5 Proposition 3.5 . . . 155
1.4.6 Retractions and extensions . . . 162
1.4.7 Definition 3.6 . . . 163
1.4.8 Proposition 3.7 . . . 165
1.4.9 Proposition 3.8 . . . 182
1.4.10 Lemma 3.9 . . . 192
1.4.11 Proposition 3.10 . . . 196

1.4.12 Definition 3.11: Projection space . . . 201
1.4.13 Proposition 3.12 . . . 201
1.4.14 Proposition 3.13 . . . 203
1.4.15 Proposition 3.14 . . . 206
1.5 Inverse limits . . . 213
1.5.1 The inverse system . . . 215
1.5.2 projLE . . . 216
1.5.3 projection . . . 218
1.5.4 Projections from the limit . . . 219
1.5.5 Embeddings along the tower . . . 220
1.5.6 Coordinates of an embedding . . . 221
1.5.7 Embeddings into the limit . . . 223
1.5.8 The mediating map . . . 226
1.5.9 inverseLimitLE . . . 228
1.5.10 inverseLimitLT . . . 229
1.5.11 The limit lattice . . . 230
1.5.12 inverseLimitTopology . . . 234
1.5.13 Proposition 4.1 . . . 238
1.5.14 Proposition 4.2 . . . 239
1.5.15 Corollary 4.3 . . . 240
1.5.16 The function space tower . . . 242
1.5.17 The functorial form . . . 272
1.5.18 Application . . . 273
1.5.19 Two projections . . . 273
1.5.20 Embedding every space . . . 273
1.5.21 Other functors . . . 274
1.5.22 Subspaces of a limit . . . 274
1.6 Correction . . . 275

2 Datatypes as Lattices (1976) 277
2.1 Introduction . . . 277
2.1.1 Historical note . . . 279
2.2 Continuous functions . . . 279
2.2.1 Introduction . . . 280
2.2.2 e . . . 282
2.2.3 pair . . . 284
2.2.4 Continuous . . . 287
2.2.5 Graph . . . 290
2.2.6 FixedPoint . . . 292
2.2.7 Embedding . . . 297
2.3 Computability and definability . . . 306
2.3.1 Historical note . . . 306
2.3.2 Meaning . . . 306
2.3.3 LAMBDA . . . 310
2.3.4 Theorem 2.1 . . . 321
2.3.5 Theorem 2.2 . . . 322

2.3.6 Theorem 2.3 . . . 325
2.3.7 Theorem 2.4 . . . 326
2.3.8 The combinator Y . . . 329
2.3.9 Theorem 2.5 . . . 332
2.3.10 The graph model . . . 338
2.3.11 Elementary definitions . . . 340
2.3.12 Sequences . . . 343
2.3.13 Distributive functions . . . 352
2.3.14 Primitive recursion . . . 359
2.3.15 Definition (computable) . . . 362
2.3.16 Computable functions . . . 362
2.3.17 Definability . . . 363
2.3.18 A law of Y . . . 375
2.4 Retracts and data types . . . 379
2.5 Closure operations and algebraic lattices . . . 387
2.6 Subsets and their classification . . . 395
2.7 Total functions and functionality . . . 634
2.8 Enumeration and degrees . . . 809

3 Neighborhood Systems (1980) 951
3.1 Introduction . . . 952
3.2 Domains given by neighbourhoods . . . 953
3.2.1 Introduction . . . 954
3.2.2 Definition 1.1 — neighbourhood system . . . 955
3.2.3 Factoid 1.1 — empty intersection is delta; recursive finite intersection . . . 956
3.2.4 Example 1.2 — two-token domain . . . 958
3.2.5 Example 1.3 — three-step chain . . . 959
3.2.6 Example 1.4 — finite binary tree . . . 960
3.2.7 Factoid 1.4a — nested or disjoint . . . 962
3.2.8 Example 1.5 — all nonempty subsets . . . 963
3.2.9 Factoid 1.5 — consistent iff nonempty; equivalent sequences same limit . . . 964
3.2.10 Definition 1.6 — ideal elements . . . 966
3.2.11 Definition 1.7 — principal filter . . . 967
3.2.12 Factoid 1.7 — principals are one-one; inclusion-reversing principals; union of principal filters . . . 968
3.2.13 Definition 1.8 — approximation and totality . . . 969
3.2.14 Factoid 1.8 — bottom element; bottom is least; finite filters are principal; prefix order; union of finite approximations . . . 970
3.2.15 Examples 1.2–1.5 (Revisited) — finite examples revisited . . . 972
3.2.16 Definition 1.9 — isomorphic domains . . . 973
3.2.17 Theorem 1.10 — basic open neighbourhoods . . . 974
3.2.18 Theorem 1.11 — intersections and directed unions . . . 976
3.2.19 Exercise 1.12 — final segments of integers . . . 978
3.2.20 Exercise 1.13 — infinite binary tree . . . 979
3.2.21 Exercise 1.14 — finite nonempty subsets . . . 980
3.2.22 Exercise 1.15 — finite elements without chains . . . 980

3.2.23 Exercise 1.16 — cofinite integer subsets . . . 981
3.2.24 Exercise 1.17 — rational open intervals . . . 982
3.2.25 Exercise 1.18 — consistency of neighbourhood families . . . 983
3.2.26 Exercise 1.19 — positive neighbourhood systems . . . 984
3.2.27 Exercise 1.20 — upward closed neighbourhoods . . . 985
3.2.28 Exercise 1.21 — complete neighbourhood systems . . . 986
3.2.29 Exercise 1.22 — topology of a domain . . . 987
3.2.30 Exercise 1.23 — decidable total elements . . . 988
3.2.31 Exercise 1.24 — extending partial elements . . . 989
3.2.32 Exercise 1.25 — final segments of ordinals . . . 989
3.2.33 Exercise 1.26 — ideals of a ring . . . 990
3.2.34 Exercise 1.27 — suprema of bounded sets . . . 991
3.3 Mappings between domains . . . 992
3.3.1 Introduction . . . 992
3.3.2 Definition 2.1 — approximable mapping . . . 993
3.3.3 Proposition 2.2 — elementwise action . . . 994
3.3.4 Example 2.3 — parity of leading zeros . . . 995
3.3.5 Example 2.4 — erase a run of ones . . . 997
3.3.6 Theorem 2.5 — category of approximable maps . . . 998
3.3.7 Proposition 2.6 — identity and composition . . . 999
3.3.8 Theorem 2.7 — isomorphisms are approximable . . . 1001
3.3.9 Lecture II exercises . . . 1002
3.3.10 Exercise 2.8 — determined by finite elements . . . 1002
3.3.11 Exercise 2.9 — directed union formula . . . 1003
3.3.12 Exercise 2.10 — intersection of two maps . . . 1004
3.3.13 Exercise 2.11 — directed unions of elements . . . 1005
3.3.14 Exercise 2.12 — directed unions of maps . . . 1006
3.3.15 Exercise 2.13 — approximable means continuous . . . 1007
3.3.16 Exercise 2.14 — isomorphisms of neighbourhoods . . . 1008
3.3.17 Exercise 2.15 — opens classified by maps . . . 1010
3.3.18 Exercise 2.16 — prefixing is approximable . . . 1011
3.3.19 Exercise 2.17 — equations for erase-ones . . . 1011
3.3.20 Exercise 2.17 — uniqueness of the erase-ones map . . . 1012
3.3.21 Exercise 2.18 — doubling binary digits . . . 1013
3.3.22 Exercise 2.19 — maps of two arguments . . . 1014
3.3.23 Exercise 2.20 — powerset of the integers . . . 1015
3.3.24 Exercise 2.21 — finite and infinite sequences . . . 1016
3.3.25 Exercise 2.22 — domains from closure properties . . . 1017
3.4 Domain constructs . . . 1019
3.4.1 Introduction . . . 1019
3.4.2 Definition 3.1 — product of systems . . . 1019
3.4.3 Proposition 3.2 — elements of a product . . . 1020
3.4.4 Definition 3.3 — projection mappings . . . 1022
3.4.5 Proposition 3.4 — pairing and projections . . . 1023
3.4.6 Theorem 3.5 — separate approximability . . . 1025

3.4.7 Lemma 3.6 — constant functions . . . 1026
3.4.8 Proposition 3.7 — closure under substitution . . . 1027
3.4.9 Definition 3.8 — function space . . . 1029
3.4.10 Proposition 3.9 — consistent step neighbourhoods . . . 1030
3.4.11 Theorem 3.10 — elements are mappings . . . 1032
3.4.12 Theorem 3.11 — evaluation combinator . . . 1033
3.4.13 Theorem 3.12 — currying . . . 1035
3.4.14 Theorem 3.13 — pointwise order of maps . . . 1037
3.4.15 Exercise 3.14 — tagged product of tokens . . . 1038
3.4.16 Exercise 3.15 — product isomorphisms . . . 1039
3.4.17 Exercise 3.16 — infinite sequences of elements . . . 1040
3.4.18 Exercise 3.17 — embedding binary sequences . . . 1041
3.4.19 Exercise 3.18 — separated sum . . . 1042
3.4.20 Exercise 3.19 — induced maps on constructs . . . 1043
3.4.21 Exercise 3.20 — sum and product functors . . . 1045
3.4.22 Exercise 3.21 — identity of step neighbourhoods . . . 1046
3.4.23 Exercise 3.22 — composition combinator . . . 1047
3.4.24 Exercise 3.23 — cartesian closed category . . . 1048
3.4.25 Exercise 3.24 — function-space isomorphisms . . . 1049
3.4.26 Exercise 3.25 — opens form a domain . . . 1050
3.4.27 Exercise 3.26 — conditional combinator . . . 1051
3.4.28 Exercise 3.27 — function space via closure . . . 1052
3.4.29 Exercise 3.28 — minimal step function . . . 1053
3.5 Fixed points and recursion . . . 1054
3.5.1 Introduction . . . 1054
3.5.2 Theorem 4.1 — least fixed point . . . 1055
3.5.3 Theorem 4.2 — fix combinator . . . 1056
3.5.4 Example 4.3 — partial functions on integers . . . 1058
3.5.5 Example 4.4 — sequence domain . . . 1062
3.5.6 Definition 4.5 — Peano axioms . . . 1065
3.5.7 Theorem 4.6 — Peano models isomorphic . . . 1066
3.5.8 Lecture IV exercises . . . 1068
3.5.9 Exercise 4.7 — fixed point above a seed . . . 1068
3.5.10 Exercise 4.8 — fixed-point induction . . . 1069
3.5.11 Exercise 4.9 — fix as a fixed point . . . 1070
3.5.12 Exercise 4.10 — domain above an element . . . 1071
3.5.13 Exercise 4.11 — characterizing the fix combinator . . . 1072
3.5.14 Exercise 4.12 — no greatest fixed point . . . 1073
3.5.15 Exercise 4.13 — avoiding the natural numbers . . . 1073
3.5.16 Exercise 4.14 — greatest powerset fixed point . . . 1075
3.5.17 Exercise 4.15 — maximal fixed points . . . 1075
3.5.18 Exercise 4.16 — optimal fixed point . . . 1076
3.5.19 Exercise 4.17 — generated submonoid . . . 1077
3.5.20 Exercise 4.18 — checking the number domain . . . 1078
3.5.21 Exercise 4.19 — Peano axioms for sequences . . . 1079

3.5.22 Exercise 4.20 — fix of a composite . . . 1080
3.5.23 Exercise 4.21 — order as a fixed point . . . 1081
3.5.24 Exercise 4.22 — inductive subset of a model . . . 1082
3.5.25 Exercise 4.23 — commuting with the iterates . . . 1083
3.5.26 Exercise 4.24 — Schroeder-Bernstein theorem . . . 1083
3.5.27 Exercise 4.25 — unary sequence domain . . . 1084
3.6 Typed λ-calculus . . . 1085
3.6.1 Introduction . . . 1085
3.6.2 Theorem 5.1 — terms denote approximable maps . . . 1089
3.6.3 Theorem 5.2 — beta conversion . . . 1091
3.6.4 Proposition 5.3 — simultaneous fixed points . . . 1092
3.6.5 Proposition 5.4 — fixed point under a parameter . . . 1094
3.6.6 Table 5.5 — table of combinators . . . 1095
3.6.7 Theorem 5.6 — partial recursive functions . . . 1096
3.6.8 Exercise 5.7 — currying the lambda notation . . . 1099
3.6.9 Exercise 5.8 — combinatory completeness . . . 1100
3.6.10 Exercise 5.9 — common fixed points . . . 1100
3.6.11 Exercise 5.10 — smash product . . . 1101
3.6.12 Exercise 5.11 — stack combinators . . . 1102
3.6.13 Exercise 5.12 — while combinator . . . 1103
3.6.14 Exercise 5.13 — pairing function on numbers . . . 1104
3.6.15 Exercise 5.13 — powerset isomorphisms . . . 1105
3.6.16 Exercise 5.14 — functions as graphs . . . 1105
3.6.17 Exercise 5.15 — star of a word . . . 1106
3.6.18 Exercise 5.16 — negation of sequences . . . 1107
3.7 Domain equations . . . 1108
3.7.1 Introduction . . . 1109
3.7.2 Example 6.1 — indefinite product . . . 1110
3.7.3 Example 6.2 — sequence domain equations . . . 1115
3.7.4 Definition 6.3 — functor . . . 1118
3.7.5 Definition 6.4 — algebra for a functor . . . 1120
3.7.6 Definition 6.5 — initial algebra . . . 1121
3.7.7 Proposition 6.6 — uniqueness of initial algebras . . . 1122
3.7.8 Proposition 6.7 — functor preserves initiality . . . 1123
3.7.9 Definition 6.8 — continuity on maps . . . 1124
3.7.10 Theorem 6.9 — homomorphism from initial algebra . . . 1125
3.7.11 Definition 6.10 — subdomain . . . 1127
3.7.12 Proposition 6.11 — lattice of subsystems . . . 1128
3.7.13 Proposition 6.12 — projection pair . . . 1129
3.7.14 Definition 6.13 — continuity on domains . . . 1130
3.7.15 Theorem 6.14 — existence of initial algebras . . . 1132
3.7.16 Lemma 6.15 — subdomains from projection pairs . . . 1135
3.7.17 Theorem 6.16 — initial algebra is minimal . . . 1137
3.7.18 Lecture VI exercises . . . 1139
3.7.19 Exercise 6.17 — algebras for sequence domains . . . 1139

3.7.20 Exercise 6.18 — infinite product as initial . . . 1140
3.7.21 Exercise 6.19 — strict sum and product . . . 1141
3.7.22 Exercise 6.20 — tokens of a functor . . . 1143
3.7.23 Exercise 6.21 — coalesced sum and smash . . . 1144
3.7.24 Exercise 6.22 — equations for the integers . . . 1145
3.7.25 Exercise 6.23 — syntactic expression domain . . . 1146
3.7.26 Exercise 6.24 — recursive domain equations . . . 1147
3.7.27 Exercise 6.25 — projection pair laws . . . 1148
3.7.28 Exercise 6.26 — lifting a domain . . . 1149
3.7.29 Exercise 6.27 — which embeddings hold . . . 1150
3.7.30 Exercise 6.28 — finite embeddings cancel . . . 1151
3.7.31 Exercise 6.29 — infinitary sum and product . . . 1152
3.8 Computability in effectively given domains . . . 1153
3.8.1 Introduction . . . 1154
3.8.2 Definition 7.1 — computable presentation . . . 1154
3.8.3 Definition 7.2 — computable mapping . . . 1156
3.8.4 Proposition 7.3 — computable maps form a category . . . 1157
3.8.5 Theorem 7.4 — sum and product effective . . . 1159
3.8.6 Theorem 7.5 — function space effective . . . 1161
3.8.7 Theorem 7.6 — fix is computable . . . 1163
3.8.8 Proposition 7.7 — lists effectively given . . . 1165
3.8.9 Example 7.8 — powerset effectively given . . . 1167
3.8.10 Definition 7.9 — power domain . . . 1168
3.8.11 Proposition 7.10 — power domain effective . . . 1170
3.8.12 Definition 7.11 — finite sets of elements . . . 1171
3.8.13 Proposition 7.12 — finite sets are approximable . . . 1173
3.8.14 Lecture VII exercises . . . 1174
3.8.15 Exercise 7.13 — axiomatic neighbourhood structure . . . 1174
3.8.16 Exercise 7.14 — primitive recursive witnesses . . . 1176
3.8.17 Exercise 7.15 — further constructs effective . . . 1177
3.8.18 Exercise 7.16 — curry as an enumeration . . . 1178
3.8.19 Exercise 7.17 — recursion over lists . . . 1178
3.8.20 Exercise 7.18 — effective isomorphism . . . 1180
3.8.21 Exercise 7.19 — power domain functor . . . 1181
3.8.22 Exercise 7.20 — union on power domains . . . 1182
3.8.23 Exercise 7.21 — distributing the power domain . . . 1183
3.8.24 Exercise 7.22 — domain of formal languages . . . 1184
3.8.25 Exercise 7.23 — graph and fun computable . . . 1185
3.8.26 Exercise 7.24 — LUCID history domain . . . 1186
3.9 Retracts of the universal domain . . . 1187
3.9.1 Introduction . . . 1188
3.9.2 Definition 8.1 — retraction . . . 1189
3.9.3 Proposition 8.2 — retractions from subdomains . . . 1189
3.9.4 Definition 8.3 — projections . . . 1191
3.9.5 Examples 8.4 — check, fade, and smash . . . 1192

3.9.6 Theorem 8.5 — finitary projection test . . . 1196
3.9.7 Theorem 8.6 — sub combinator . . . 1197
3.9.8 Definition 8.7 — interval presentation of U . . . 1199
3.9.9 Theorem 8.8 — universality of U . . . 1203
3.9.10 Definition 8.9 — constructs on projections . . . 1207
3.9.11 Proposition 8.10 — constructs preserve projections . . . 1212
3.9.12 Lecture VIII exercises . . . 1214
3.9.13 Exercise 8.11 — retraction on intervals . . . 1215
3.9.14 Exercise 8.12 — integer presentation of U . . . 1216
3.9.15 Exercise 8.13 — Boolean-algebra filters . . . 1229
3.9.16 Exercise 8.14 — closure operators . . . 1231
3.9.17 Exercise 8.15 — domain of subsystems . . . 1233
3.9.18 Exercise 8.16 — order of projections . . . 1238
3.9.19 Exercise 8.17 — explicit embeddings into U . . . 1240
3.9.20 Exercise 8.18 — missing proofs of 8.10 . . . 1243
3.9.21 Exercise 8.19 — closure under sum and product . . . 1246
3.9.22 Exercise 8.20 — self-embeddings of a domain . . . 1248
3.9.23 Exercise 8.21 — lists of a projection . . . 1250
3.9.24 Exercise 8.22 — comparing B and C . . . 1253
3.9.25 Exercise 8.23 — initial algebra inside U . . . 1255
3.9.26 Exercise 8.24 — coupled domain equations . . . 1257
3.9.27 Exercise 8.25 — reflexive function space . . . 1259
3.9.28 Exercise 8.26 — untyped calculus in U . . . 1307
3.9.29 Exercise 8.27 — infinite cartesian products . . . 1309

Dependency diagram. The four papers stand on their own. The bridge theorems import continuous lattices, neighborhood systems, and information systems. Each box is one chapter. The arrowhead is on the chapter that imports. The number is how many direct imports. Datatypes as lattices and the references have no arrow.

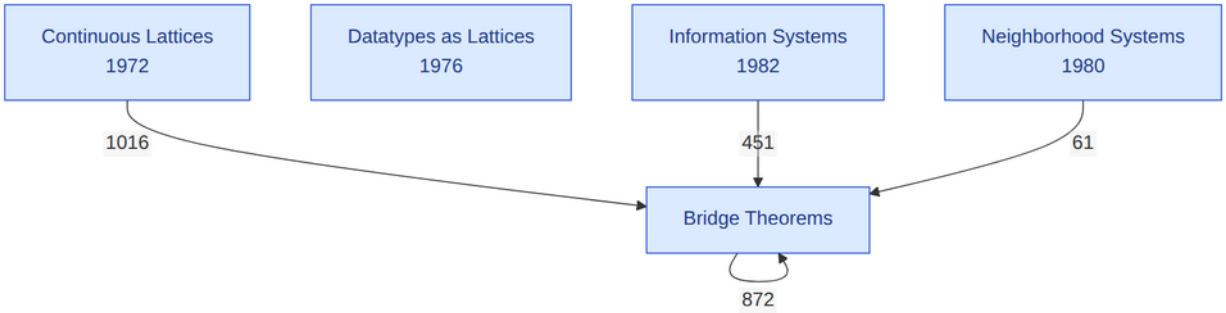

Figure 1: Abstract.

1 Continuous Lattices (1972)

Starting from the topological point of view a certain wide class of T_0-spaces is introduced having a very strong extension property for continuous functions with values in these spaces. It is then shown that all such spaces are complete lattices whose lattice structure determines the topology - these are the *continuous lattices* - and every such lattice has the extension property. With this foundation the lattices are studied in detail with respect to projections, subspaces, embeddings, and constructions such as products, sums, function spaces, and inverse limits. The main result of the paper is a proof that every topological space can be embedded in a continuous lattice which is homeomorphic (and isomorphic) to its own function space. The function algebra of such spaces provides mathematical models for the Church-Curry λ-calculus.

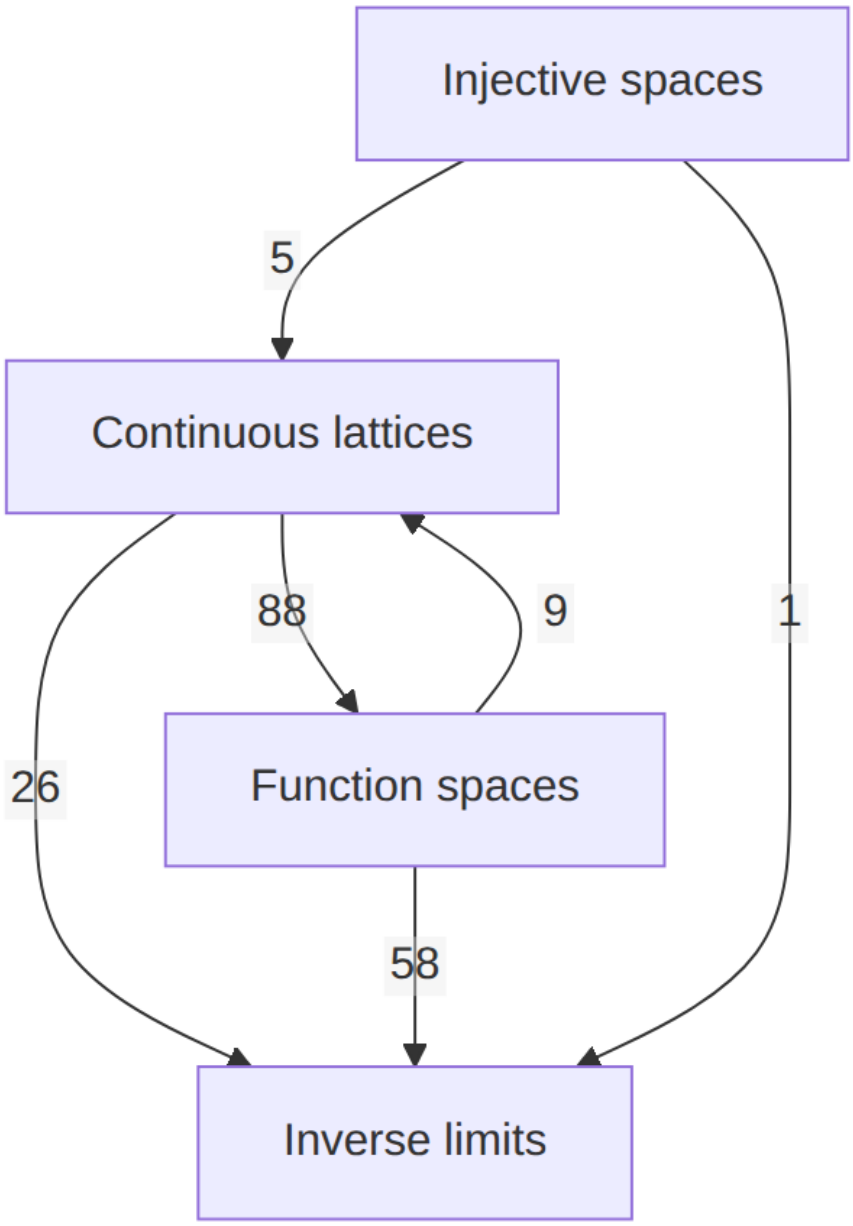

Figure 2: Continuous Lattices (1972).

1.1 Introduction

Through a roundabout chain of mathematical events I have become interested in T_0-spaces, those topological spaces satisfying the weakest separation axiom to the effect that two distinct points cannot share the same system of open neighborhoods. These spaces seem to have been originally suggested by Kolmogoroff and were introduced first in Alexandroff and Hopf (1935). Subsequent topology textbooks have dutifully recorded the definition but without much enthusiasm: mainly the idea is introduced to provide exercises.

In the book Čech (1966) for example, T_0-spaces are called *feebly semi-separated spaces*, which surely is a term expressing mild contempt. Some interest has been shown in finite T_0-spaces (finite T_1-spaces are necessarily discrete), but generally topology seems to go better under at least the Hausdorff separation axiom. The reason for this is no doubt the strong motivation we get from geometry, where points *are* points and where distinct points *can* be separated.

What I hope to show in this paper is that from a less geometric point of view T_0-spaces can be not only interesting but also natural. The interest for me lies in the construction of *function spaces*, and the main result is the production of a large number of T_0-spaces D such that D and $[D \to D]$ are *homeomorphic*. Here $[D \to D]$ is the space of all continuous functions from D into D with the topology of pointwise convergence (the product topology). It will be shown that every space can be embedded in such a space D, and that D can be chosen to have quite strong extension properties for D-valued continuous functions. These properties make D most convenient for applications to logic and recursive function theory, which was the author's original motivation. Some of the facts about these spaces seem to be most easily proved with the aid of some lattice theory, a circumstance that throws new light on the connections between topology and lattices. In fact, the required spaces are at the same time complete lattices whose topology is determined by the lattice structure in a special way, whence my title.

1.2 Injective spaces

All spaces are T_0-spaces, and we begin by defining a class of spaces to be called *injective*.

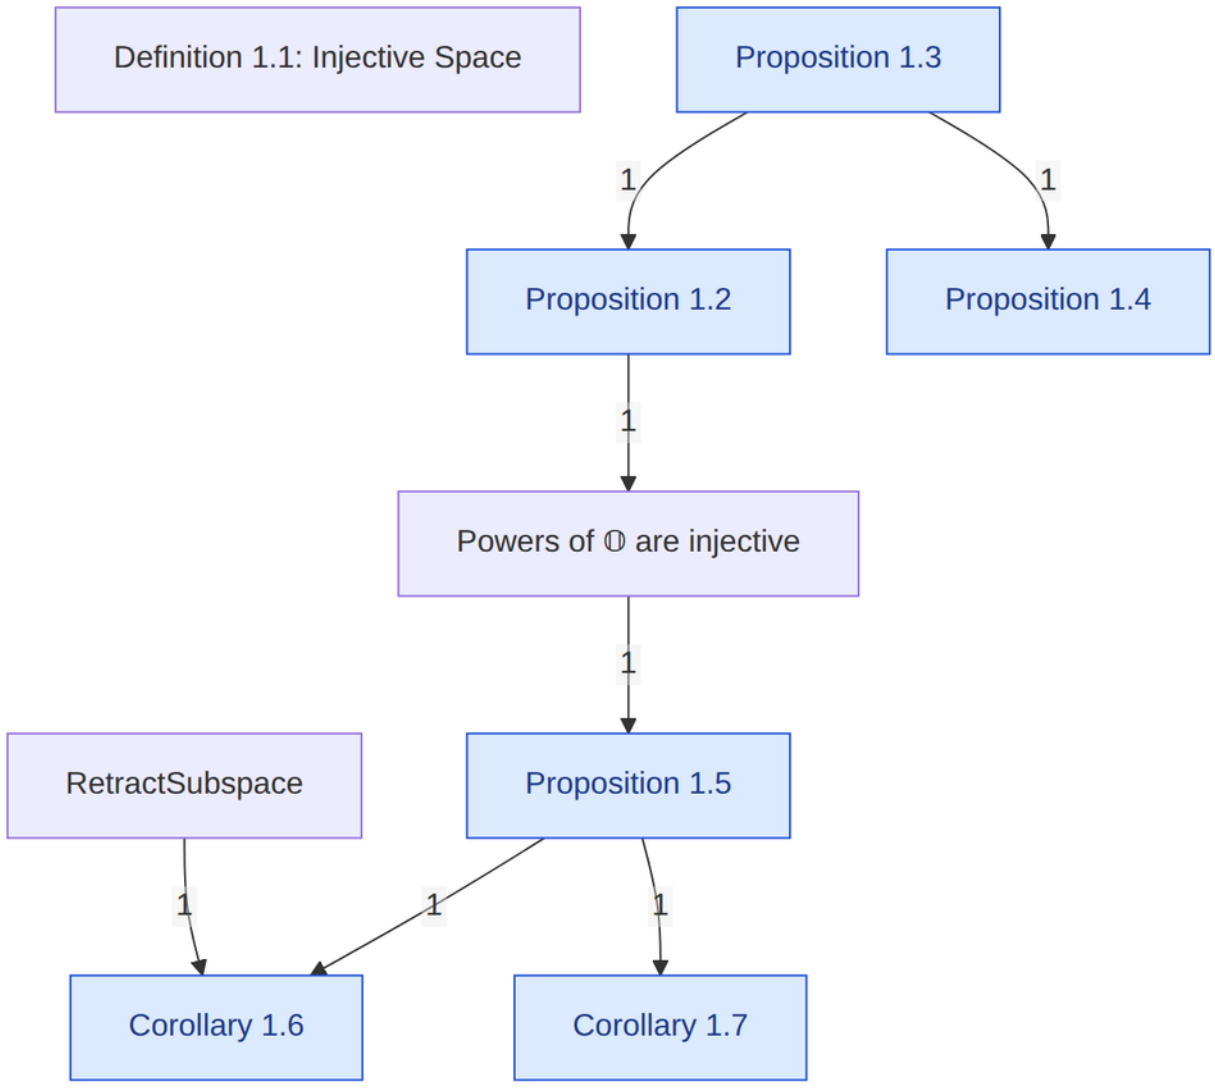

Figure 3: Injective spaces.

1.2.1 Definition 1.1: Injective Space

1.1 Definition. A T_0-space D is *injective* iff for arbitrary spaces X and Y if $X \subseteq Y$ as a subspace, then every continuous function $f : X \to D$ can be extended to a continuous function $\bar{f} : Y \to D$. As a diagram we have:

$$X \subseteq Y$$
$$X \xrightarrow{f} D$$
$$Y \xrightarrow{\bar{f}} D$$

Some people will object to this terminology because I use the subspace relationship rather than a monomorphism in the category of T_0-spaces and continuous maps. However, only the trivial 1-point space

is injective in the sense of monomorphisms in that category, and so the notion is uninteresting. If the reader prefers another terminology, I do not mind. As we shall see these spaces have very strong retraction properties.

A slightly less trivial example of an injective space is the 2-point space $\mathbb{O}$ with "points" $\bot$ and $\top$ where $\top$ is open but $\bot$ is not. (This space is sometimes called the *Sierpinski Space*.)

1.2.2 Proposition 1.2

1.2 Proposition. The space $\mathbb{O}$ is injective.

Proof: As is obvious, the continuous maps $f : X \to \mathbb{O}$ are in a one-one correspondence with the open subsets of X (consider $f^{-1}(\top)$). If $X \subseteq Y$ as a subspace, then an open subset of X is the restriction of some open subset of Y. Thus any $f : X \to \mathbb{O}$ can be extended to $\bar{f} : Y \to \mathbb{O}$. □

1.2.3 Proposition 1.3

1.3 Proposition. The Cartesian product of any number of injective spaces is injective under the product topology.

Proof: The argument is standard. A map into the product can be projected onto each of the factors. Each of these projections can be extended. Then the separate maps can be put together again to make the required extended map into the product. □

We now have a large number of injective spaces, and further examples could be found using the next fact.

1.2.4 Powers of $\mathbb{O}$ are injective

Scott's proof of **Proposition 1.5** uses the space `D = 𝕆^[U+1D512]`, a Cartesian power of the two-point Sierpiński space $\mathbb{O}$. That power is injective because:

- **Proposition 1.2** — the single space $\mathbb{O}$ (`Prop` with the Sierpiński topology) is injective;
- **Proposition 1.3** — a product of injective spaces is injective under the product topology.

For any index type ι, the Lean power is $\iota \to$ `Prop` with the product topology. The lemma `isInjectiveSpace_sierpinski_power` is exactly "apply 1.3 to $\mathtt{i} \mapsto$ `Prop` using 1.2 at each index." In Proposition 1.5 we take $\iota =$ `Opens X`.

1.2.5 Proposition 1.4

1.4 Proposition. A retract of an injective space is injective.

Proof: Let D be injective. By a retract of D we understand a subspace $D' \subseteq D$ for which there exists a retraction map $j : D \to D'$ such that

$$D' = \{x \in D : j(x) = x\}.$$

Then if $f : X \to D'$ and $X \subseteq Y$, we have $f : X \to D$ as a continuous map also. Taking $\bar{f} : Y \to D$, we have only to form

$$j \circ \bar{f} : Y \to D'$$

to show that D' is injective. □

The relationship between arbitrary T_0-spaces and the injective spaces is given by the embedding theorem.

1.2.6 Proposition 1.5

1.5 Proposition. Every T_0-space can be embedded in an injective space; in fact, in a Cartesian power of the 2-element space $\mathbb{O}$.

Proof: The proof is well known (cf. Čech (1966), Theorem 26B.9, p. 484.) But we give the argument for completeness sake. Let X be the given space, and let $\mathfrak{O}$ be the class of open subsets of X. Let

$$D = \mathbb{O}^{\mathfrak{O}}$$

be the Cartesian power of $\mathbb{O}$. Then D is injective by 1.3. Define the map $e : X \to D$ by:

$$e(x)(U) = \begin{cases} \top & \text{if } x \in U, \\ \bot & \text{if } x \notin U, \end{cases}$$

for $x \in X$ and $U \in \mathfrak{O}$. This map e is continuous in view of the topology given to $\mathbb{O}$ and to D. The map e is one-one, because X is T_0. Finally, if $U \subseteq X$ is open, then

$$e(U) = e(x) : x \in U \quad = e(x) : e(x)(U) = \top = e(X) \cap t \in D : t(U) \in \top,$$

which shows that the image $e(U)$ is open in the subspace $e(X) \subseteq D$. Therefore $e : X \to D$ is an embedding of X as a subspace in D. □

1.2.7 RetractSubspace

Corollary 1.6 characterizes injective spaces as retracts of powers of $\mathbb{O}$. The Lean development packages "`D` is a subspace of a larger space and the inclusion splits by a continuous retraction" as `RetractSubspace D' D`: a continuous section `D' → D` that is an embedding, together with a retraction `D → D'` fixing the subspace pointwise.

Corollary 1.6 then states that `D` is injective if and only if it is such a retract of some power `ι → Prop`.

1.2.10 Absolute retracts

As a result of these very elementary considerations, the injective spaces could be called *absolute retracts*, if one remembers to modify the standard definitions by using *arbitrary* subspaces rather than just *closed* subspaces. Note too that it is easy to show that the only continuous maps $e : X \to Y$ for which the extension property

$$X \xrightarrow{e} Y$$

$$X \xrightarrow{f} \mathbb{O}$$

$$Y \xrightarrow{\bar{f}} \mathbb{O}$$

could hold for *all* continuous $f : X \to \mathbb{O}$ are embeddings as subspaces.

Thus it would seem that we have a reasonably good initial grasp of the notion of injective spaces, but further constructions are considerably facilitated by the introduction of the lattice structure.

1.3 Continuous lattices

Every T_0-space becomes a partially ordered set under the definition:

$$x \sqsubseteq y \text{ iff whenever } x \in U \text{ and } U \text{ is open, then } y \in U.$$

Indeed, though this relation is reflexive and transitive, the condition that it be *antisymmetric* is exactly equivalent to the T_0-axiom.

In the converse direction, every partially ordered set $\langle X, \sqsubseteq \rangle$ can be so obtained, for we have only to define $U \subseteq X$ as being open if it satisfies the condition:

(i) whenever $x \in U$ and $x \sqsubseteq y$, then $y \in U$.

The axioms for partial order make X a T_0-space, because for any $y \in X$ the set

$$\{x \in X : x \not\sqsubseteq y\}$$

is open. This connection is not very interesting, however.

What *is* interesting in topological spaces is *convergence* and the properties of *limit points*. We shall discuss limits in terms of *nets*, in particular in terms of *monotone nets*. A monotone net in a T_0-space X is a function

$$x : I \to X$$

where $\langle I, \leq \rangle$ is a directed set and where $i \leq j$ implies $x_i \sqsubseteq x_j$ for all $i, j \in I$. In a T_1-space a monotone net is constant (hence, uninteresting) because the $\sqsubseteq$-relation is the identity. As usual (cf. Kelley (1955), p.66) we say that a net x *converges* to an element y iff whenever U is open and $y \in U$, then for some $i \in I$ we have $x_j \in U$ for all $j \geq i$. Note that a monotone net x converges to each of its terms x_i. Suppose that a monotone net x converges to an element y which is an upper bound to all the terms of x. Then y must be the *least upper bound*, which we write as:

$$y = \bigsqcup \{x_i : i \in I\}.$$

To see this, assume that z is any other upper bound with $x_i \sqsubseteq z$ for all $i \in I$. If U is open and $y \in U$, then $x_i \in U$ for some $i \in I$. But then $z \in U$, and so $y \sqsubseteq z$ follows.

We shall find that most of the facts about the topology of the spaces we are concerned with here can be expressed in terms of least upper bounds (lubs). It is not always the case, however, that lubs are limits. Thus, for a partially ordered set X, we impose a further restriction on its topology beyond condition (i) for saying when a subset U is open:

(ii) whenever $S \subseteq X$ is *directed*, $\bigsqcup S$ exists, and $\bigsqcup S \in U$, then $S \cap U \neq \emptyset$.

By a directed subset of X we of course mean that it is directed in the sense of the partial ordering $\sqsubseteq$. Note that in this paper directed sets are always *non-empty*. The sets satisfying (i) and (ii) form the *induced topology* on a partially ordered set X, which is still a T_0-space because the sets $\{x \in X : x \not\sqsubseteq y\}$ remain open even in the sense of (ii). Obviously a directed set $S \subseteq X$ can be regarded as a net, and now in view of (ii) it follows that S converges to $\bigsqcup S$ — if this lub exists. We can summarize this discussion as follows.

1.3.2 Way-below relation

Our main interest will lie with those partially ordered sets in which every subset has a lub: namely, *complete lattices*. If D is such a space we write $\bot = \bigsqcup \emptyset$ and $\top = \bigsqcup D$ for the smallest and largest elements (read: bottom and top). As is well known, greatest lower bounds must exist, for:

$$\sqcap S = \bigsqcup \{x \in D : x \sqsubseteq y\} \text{ for all } y \in S$$

gives the definition.

Given a complete lattice D we define

$$x \ll y \text{ iff } y \in \text{Int}\{z \in D : x \sqsubseteq z\},$$

where the interior is taken in the sense of the induced topology. The relation $x \ll y$ behaves somewhat like a strict ordering relation; at least its meaning is clearly that y should be definitely larger than x in the partial ordering. Such a relation has many pleasant properties.

The primary purpose of introducing it is to provide a simple definition for the kind of spaces that are most useful to us. We first mention the most elementary features of this relation.

1.3.3 Proposition 2.2

2.2 Proposition. In a complete lattice D we have:

(i) $\bot \ll x$;

(ii) $x \ll z$ and $y \ll z$ imply $x \sqcup y \ll z$;

(iii) $x \ll y \sqsubseteq z$ implies $x \ll z$;

(iv) $x \sqsubseteq y \ll z$ implies $x \ll z$;

(v) $x \ll y$ implies $x \sqsubseteq y$;

(vi) $x \ll x$ iff $\{z \in D : x \sqsubseteq z\}$ is open;

(vii) if $S \subseteq D$ is directed, then $x \ll \bigsqcup S$ iff $x \ll y$ for some $y \in S$. $\square$

The proofs of these statements can be safely left to the reader.

1.3.5 Proposition 2.4

2.4 Proposition. A complete lattice D is continuous iff for every $y \in D$ we have:

$$y = \bigsqcup \{ \sqcap U : y \in U \},$$

where U ranges over the open subsets of D.

Proof: Suppose D is continuous. If $y \in D$ and $x \ll y$, then let $U = \{\text{Int} z : x \sqsubseteq z\}$, an open set. Now $y \in U$ by definition, and $\{U \subseteq z : x \sqsubseteq z\}$. Thus,

$$x \sqsubseteq \sqcap U \sqsubseteq y.$$

It easily follows by lattice theory that the equation of 2.3 implies that of 2.4.

In the converse direction we have only to note that if U is open and $y \in U$, then $\sqcap U \ll y$. The implication from 2.4 to 2.3 results at once. □

1.3.6 Limits and convergence

What is the idea of this definition? A continuous lattice is more special than a complete lattice: not only are lubs to be limits but every element must be a limit from below. This rather rough remark can be made more precise. In any complete lattice D define the *principal limit* of a net $x : I \to D$ by the formula:

$$\lim\langle x_i : i \in I\rangle = \bigsqcup\{\sqcap x_j : j \geq i : i \in I\}.$$

Then specify that x converges to $y \in D$ iff

$$y \sqsubseteq \lim\langle\{x_i : i \in I\rangle\}.$$

Having a notion of convergence, we can then say that $U \subseteq D$ is open iff every net converging to an element of U is eventually in U. This gives nothing more than what we have called the induced topology above, as is easily checked. But now being in possession of a topology, we can redefine convergence in the usual way. Question: when do the two notions of convergence agree? Answer: if and only if D is a continuous lattice.

For obviously by construction the limit definition of convergence implies the topological. Now if D is a continuous lattice and x converges to y topologically, consider an open $U \subseteq D$ with $y \in U$. For some $i \in I$ we shall have $x_j \in U$ for all $j \geq i$. Therefore

$$\sqcap U \sqsubseteq \{\sqcap x_j : j \geq i \sqsubseteq \lim\langle x_i : i \in I\rangle\}.$$

From the formula of 2.4 it at once follows that $y \sqsubseteq \lim\langle\{x_i : i \in I\rangle\}$. Thus, in continuous lattices, we have shown that the two notions of convergence are the same.

Finally, suppose that the two notions coincide for a complete lattice D. Define a directed set $I = (U, z) : y, z \in U$, where z ranges over D and U over open subsets of D. This set is directed by the relation: $(U, z) \leq (V, w)$ iff $U \supseteq V$. Let $x : I \to D$ be given by: $x(U, z) = z$. Then x is a net converging to y topologically. But

$$\lim\langle x_i : i \in I\rangle = \bigsqcup\{\sqcap U : y \in U\}.$$

In this way we see that the assumption about the two styles of convergence implies that D is a continuous lattice in view of 2.4.

In T_0-spaces continuous functions are always monotonic (i.e. $\sqsubseteq$-preserving). For continuous lattices, by virtue of the remarks we have just made about limits, we can define the continuity of $f : D \to D'$ to mean that

$$f(\lim\langle\{x_i : i \in I\rangle) \sqsubseteq \overset{\prime}{\lim}\langle f(x_i) : i \in I\rangle\}$$

for all nets $x : I \to D$. This is all very fine, but general limits are messy to work with; we shall find it easier to state results in terms of lubs as in 2.5–2.7 below.

Before going any deeper, however, we should clear up another point about topologies. Suppose that D is any T_0-space which becomes a complete lattice under its induced partial ordering. Then it is evident from our definitions that every set open in the given topology is also open in the topology induced from the lattice structure. Question: when do the two topologies agree? Answer: a sufficient condition is that the equation:

$$y = \bigsqcup\{\sqcap U : y \in U\}$$

hold for all $y \in D$, where U ranges over the given open sets. Because in that case if V is open in the lattice sense and $y \in V$, then $\sqcap U \in V$ for some set U, open in the given sense, where $y \in U$. But $U \subseteq V$ follows, and so V is a union of given open sets and is itself open in the given topology. Of course this equation implies that D is a continuous lattice by virtue of 2.4. Notice that by the same token the sets of the form $\{y \in D : x \ll y\}$ will form a basis for the open sets of a continuous lattice.

hold for all $y \in D$, where U ranges over the given open sets. Because in that case if V is open in the lattice sense and $y \in V$, then $\sqcap U \in V$ for some set U, open in the given sense, where $y \in U$. But $U \subseteq V$ follows, and so V is a union of given open sets and is itself open in the given topology. Of course this equation implies that D is a continuous lattice by virtue of 2.4. Notice that by the same token the sets of the form $\{y \in D : x \ll y\}$ will form a basis for the open sets of a continuous lattice.

1.3.7 Scott maps

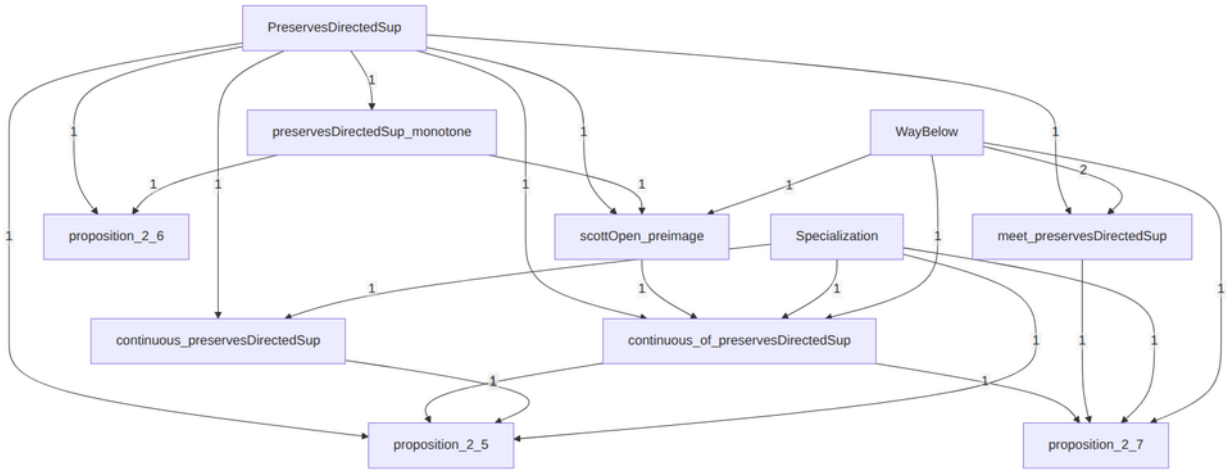

Figure 6: Scott maps.

Proposition 2.5 **2.5 Proposition.** *If D and D' are complete lattices with their induced topologies, then a function $f : D \to D'$ is continuous iff for all directed subsets $S \subseteq D$:*

$$f(\bigsqcup S) = \bigsqcup \{f(x) : x \in S\}.$$

Proof: If $f : D \to D'$ is continuous, the equation follows from the definition of continuous function and the fact that lubs are limits. Assume then that the equation holds for all directed sets S. Let $U' \subseteq D'$ be open in D' and let

$$U = \{x \in D : f(x) \in U'\}.$$

We must show that U is open in D. Note first that if $x \sqsubseteq y$, then $S = x, y$ is directed; hence,

$$f(x \sqcup y) = f(y) = f(x) \sqcup f(y),$$

so $f(x) \sqsubseteq f(y)$. Thus f is monotonic and so U satisfies condition (i). That U satisfies condition (ii) follows at once from the above equation. □

Proposition 2.6 **2.6 Proposition.** *With functions from complete lattices to complete lattices, a function of several variables is continuous in the variables jointly iff it is continuous in the variables separately.*

Proof: It will be sufficient to discuss functions of two variables. The product $D \times D'$ of two complete lattices is a complete lattice, and it is easy to check that the induced topology is the product topology. Since projection is continuous, joint continuity implies separate continuity. To check the converse suppose that

$$f : D \times D' \to D''$$

is a map where the separate continuity holds as follows:

$$f(\bigsqcup S, y) = \bigsqcup f(x, y) : x \in S$$

and

$$f(x, \bigsqcup S') = \bigsqcup \{f(x, y) : y \in S'\}$$

where $S \subseteq D$ and $S' \subseteq D'$ are directed and $x \in D$ and $y \in D'$. Let now

$$S^* \subseteq D \times D'$$

be directed in the product. The projection of S^* to D and of S^* to D' produces directed subsets $S \subseteq D$ and $S' \subseteq D'$. Note that

$$\bigsqcup S^* = (\bigsqcup S, \bigsqcup S').$$

Thus by assumption

$$f(\bigsqcup S^*) = \bigsqcup\{f(x,y) : x \in S, y \in S'\}.$$

But since S^* is directed, $x \in S$ and $y \in S'$ implies $x \sqsubseteq u$ and $y \sqsubseteq v$ for $(u,v) \in S^*$. Thus by monotonicity of f we can show

$$f(\bigsqcup S^*) = \bigsqcup\{f(u,v) : (u,v) \in S^*\}$$

and that gives the joint continuity. □

One of the justifications (by euphony at least) of the term *continuous lattice* is the fact that such spaces allow for so many continuous functions. One indication of this is the result:

Proposition 2.7 **2.7 Proposition.** *In a continuous lattice D the finitary lattice operations $\sqcup$ and $\sqcap$ are continuous.*

Proof: It is trivial to show that $\sqcup$ is continuous in every complete lattice; this is not so for $\sqcap$. In view of 2.6 we need only show

$$x \sqcap \bigsqcup S = \bigsqcup \{x \sqcap y : y \in S\}$$

for every directed $S \subseteq D$. In fact it is enough to show

$$x \sqcap \bigsqcup S \sqsubseteq \bigsqcup \{x \sqcap y : y \in S\}$$

because the opposite inequality is valid in all complete lattices. In view of the fact that D is continuous, it is enough to show that

$$t \ll x \sqcap \bigsqcup S \text{ implies } t \sqsubseteq \bigsqcup \{x \sqcap y : y \in S\}.$$

So assume $t \ll x \sqcap \bigsqcup S$. Then $t \sqsubseteq x \sqcap \bigsqcup S \sqsubseteq x$. Also $t \ll \bigsqcup S$ because $x \sqcap \bigsqcup S \sqsubseteq \bigsqcup S$. Thus $t \ll y$ for some $y \in S$ since the set

$$\{z \in D : t \ll z\}$$

is open. But then $t \sqsubseteq y$, and so $t \sqsubseteq x \sqcap y$, and the result follows. □

It is now time to provide some examples of continuous lattices.

1.3.9 Proposition 2.9

2.9 Proposition. The Cartesian product of any number of continuous lattices is a continuous lattice with the induced topology agreeing with the product topology.

1.3.10 Proposition 2.10

2.10 Proposition. A retract of a continuous lattice is a continuous lattice with the subspace topology agreeing with the induced topology.

It would seem that the continuous lattices are starting to sound suspiciously like the injective spaces. Indeed, if we can prove the following, the circle will be complete.

1.3.11 Proposition 2.11

2.11 Proposition. Every continuous lattice is an injective space under its induced topology.

1.3.12 Theorem 2.12

2.12 Theorem. The injective spaces are exactly the continuous lattices.

This theorem is an immediate consequence of the preceding results: an injective space is a retract of a power of $\mathbb{O}$. But $\mathbb{O}$ is a finite lattice $(\bot \sqsubseteq \top)$, and so the given space is a continuous lattice under its induced topology. On the other hand a continuous lattice is injective. It remains then to prove 2.9–2.11.

1.3.13 Proof of 2.9

Proof of 2.9

Let D_i for $i \in I$ be a system of continuous lattices. The product

$$D^* = \prod_{i \in I} D_i$$

is a complete lattice in the usual way and has its induced topology. Suppose $y \in D^*$ and let $i \in I$. Then $y_i \in D_i$. Since D_i is a continuous lattice

$$y_i = \bigsqcup \{x \in D_i : x \ll y_i\}.$$

For $x \in D_i$, let $[x]^i \in D^*$ be defined by:

$$[x]^i_j = \begin{cases} x & \text{if } i = j, \\ \bot & \text{if } i \neq j. \end{cases}$$

Note that since D_i is continuous we have:

$$[y_i]^i = \bigsqcup \{[x]^i : x \ll y_i\},$$

and

$$y = \bigsqcup \{[y_i]^i : i \in I\}.$$

It follows that

$$y = \bigsqcup \bigcap \{z : z_i \in U \text{ for all } i \in I,\ y_i \in U\},$$

where i ranges over I and U over the open subsets of D_i, because

$$[x]^i \sqsubseteq \bigcap \{z : z_i \in U\}, \quad \text{where } U = \{u \in D_i : x \ll u\}.$$

But the sets $\{z : z_i \in U\}$ are open in the product sense, and so

$$y = \bigsqcup \bigcap \{U : y \in U\},$$

where U ranges now over the open subsets of the product topology on D^*. By the remark following 2.4 we conclude that D^* is continuous with the lattice-induced topology being the product topology. □

1.3.14 Proof of 2.10

Proof of 2.10

Let D' be a continuous lattice and let $D \subseteq D'$ be a subspace which is a retract. We have for a suitable $j : D' \to D$,

$$D = \{x \in D' : j(x) = x\},$$

where of course j is continuous.

First a note of warning: though D is a subspace it is not a sublattice; that is, the partial ordering on D is the restriction of that of D', but the lubs of D are not those of D'. We shall have to distinguish operations by adding a prime ($'$) for those of D'.

Suppose $x, y \in D$. Let $z' = x \sqcup y \in D'$ (join taken in D') and define $z = j(z') \in D$. Now $x \sqsubseteq z'$ and $y \sqsubseteq z'$, and j is monotonic, so $x \sqsubseteq z$ and $y \sqsubseteq z$. Suppose $x \sqsubseteq w$ and $y \sqsubseteq w$ with $w \in D$. Then in D' we have $x \sqcup y \sqsubseteq w$; so $z \sqsubseteq w$ also. Hence we have shown that $z = x \sqcup y$ in D.

To show that D has a least element $\bot$ (which may be larger than the $\bot' \in D'$), we need a well-known lemma about monotonic functions: Every monotonic function on a complete lattice into itself has a least fixed point. (Cf. Birkhoff (1970), p. 115.) In our case j is monotonic and

$$\bot = \sqcap \{x \in D' : j(x) \sqsubseteq x\}$$

is the desired element in D.

Thus D is at least a semilattice with $\bot$ and $\sqcup$. To show that D is a lattice we need to show that every directed $S \subseteq D$ has a lub in D. Now we know ($S' = S$, join taken in the ambient lattice D'):

$$\bigsqcup S' \in D',$$

and this is a limit of a monotone net. So by 2.1, and the continuity of j:

$$j(\bigsqcup S') = \bigsqcup \{j(x) : x \in S\} \quad = \bigsqcup S$$

in D. In this way we now know that D is a complete lattice. We must still show that D is continuous.

Suppose $y \in D$. In D' we can write:

$$y = \bigsqcup \{x \in D' : x \ll y'\}$$

and this is the limit of a monotone net. Thus

$$j(y) = y = \bigsqcup j(x) : x \ll y, x \in D',$$

where the lub is taken in D. Note that the sets

$$U = \{z \in D : x \ll z\}$$

are open in D for each $x \in D'$. Note too that if $z \in U$, then $x \sqsubseteq z$ and so $j(x) \sqsubseteq j(z) = z$. This means that

$$j(x) \sqsubseteq \sqcap U$$

in D. We can then write in D:

$$y = \bigsqcup \{\sqcap U : y \in U\}$$

where U ranges over the open subsets of D, and so the lattice is continuous by 2.4. Inasmuch as the open sets U just used were open in the subspace topology, it follows by the remark after 2.4 that the subspace and the lattice-induced topologies coincide. □

1.3.15 Proof of 2.11

Proof of 2.11: Let D be a continuous lattice with its induced topology, and let $X \subseteq Y$ be two T_0-spaces in the subspace relation. Suppose

$$f : X \to D$$

is continuous. Define

$$\bar{f} : Y \to D$$

by the formula:

$$\bar{f}(y) = \bigsqcup \{ \sqcap \{ f(x) : x \in X \cap U \} : y \in U \},$$

where U ranges over the open subsets of Y. We need to show that $\bar{f}$ extends f and that it is continuous.

First, the continuity: Suppose that $d \in D$ and $d \ll \bar{f}(y)$; that is, $\bar{f}(y)$ belongs to a typical basic open subset of D. Since D is continuous, we can also find

$$d \ll d' \ll \bar{f}(y)$$

with $d' \in D$. From the definition of $\bar{f}$ it follows that

$$d' \sqsubseteq \sqcap \{ f(x) : x \in X \cap U \}$$

for some open $U \subseteq Y$ with $y \in U$. Thus

$$d' \sqsubseteq \bar{f}(y')$$

for all $y' \in U$ by virtue of the definition of $\bar{f}$. Since $d \ll d'$, we have also

$$d \ll \bar{f}(y')$$

for all $y' \in U$; in other words, the inverse image of the open subset of D determined by d under $\bar{f}$ is indeed open in Y, and $\bar{f}$ is thus continuous.

Next, the extension property: Note that the relationship

$$\bar{f}(x') \sqsubseteq f(x')$$

for all $x' \in X$ comes directly out of the definition of $\bar{f}$. For the converse, suppose $d \ll f(x')$ where $d \in D$. By assumption $f : X \to D$ is continuous, so

$$d \ll f(x'')$$

for all $x'' \in X \cap U$ where U is a suitable open subset of Y with $x' \in U$. In particular we have:

$$d \sqsubseteq \sqcap \{ f(x'') : x'' \in X \cap U \},$$

and so $d \sqsubseteq \bar{f}(x')$. Since $d \ll f(x')$ always implies $d \sqsubseteq \bar{f}(x')$, we see that $f(x') \sqsubseteq \bar{f}(x')$ follows by the continuity of D, and the proof is complete. □

/-- **Scott 1972, Theorem 2.12 (backward direction).** Every injective `T₀`-space is
    homeomorphic
to a continuous lattice equipped with its Scott topology.

The injective space `D` is a retract of a power `𝕆^I = (I → Prop)` of the Sierpinski
    space
(Corollary 1.6). Writing `s : D → 𝕆^I` for the embedding and `r : 𝕆^I → D` for the
    retraction,
`e := s ∘ r` is a Scott-continuous idempotent on `𝕆^I` (its topology is its Scott
    topology by
`scottTopology.sierpinskiPower`). The fixed-point set `IdemFix e` is therefore a
    continuous lattice
(`idemFix_isContinuousLattice`, via Proposition 2.10), and `d ↦ s d` is a
    homeomorphism `D ≃ₜ
IdemFix e` with inverse the retraction. -/

1.3.17 After Theorem 2.12

The lattice approach to injective spaces gives a completely "internal" characterization of them: in the first place the lattices are complete. Next we can define lattice theoretically:

$$x \ll y \quad \text{iff} \quad \text{whenever } y \sqsubseteq \bigsqcup Z \text{ and } Z \subseteq D \text{ is directed,}$$

then $x \sqsubseteq z$ for some $z \in Z$.

Finally we assume that for all $y \in D$:

$$y = \bigsqcup \{x \in D : x \ll y\}.$$

That makes D a continuous lattice with the sets $\{y \in D : x \ll y\}$ as a basis for the topology. Such T_0-spaces are injective and every injective space can be obtained in this way with the lattice structure being uniquely determined by the topology. Furthermore, as we have seen, the injective property can be exhibited, as in the proof of 2.11, by an explicit formula for extending functions.

The retract approach to injective spaces should also be considered. The Cartesian powers $\mathbb{O}^I$ are very simple spaces; indeed, as lattices these are just the Boolean algebras of *all subsets* of I (that is, isomorphic thereto). The topology has as a basis the

classes of sets containing given finite sets (the *weak topology*, cf. Nerode (1959)). A continuous function

$$j : \mathcal{P}I \to \mathcal{P}I$$

is one of "finite character" so that

$$j(X) = \bigcup j(F) : F \subseteq X$$

where $X \subseteq I$ and F ranges over *finite sets*. Such a function j is a *retraction* iff it is an *idempotent*:

$$j \circ j = j,$$

which means that the range of j is the set of fixed points of j. As we have seen

$$D = \{X \in \mathcal{P}I : j(X) = X\}$$

is a continuous lattice (under $\subseteq$ in this case), and *every* continuous lattice is isomorphic to one obtained in this way. This provides a representation theorem of sorts for continuous lattices, but it does not seem to be of too much help in proving theorems.

The reader should not forget that any space (any *given* number of spaces X, Y, ...) can be found as a *subspace* of a continuous lattice D. Since D is injective any continuous function $f : X \to Y$ can be extended to a continuous function $\bar{f} : D \to D$. Thus the continuous functions from D into D are a rich totality including *all* the structure of continuous functions on *all* the subspaces. And this remark brings us to the study of function spaces.

1.4 Function spaces

We recall the standard definition and introduce our notation for function spaces.

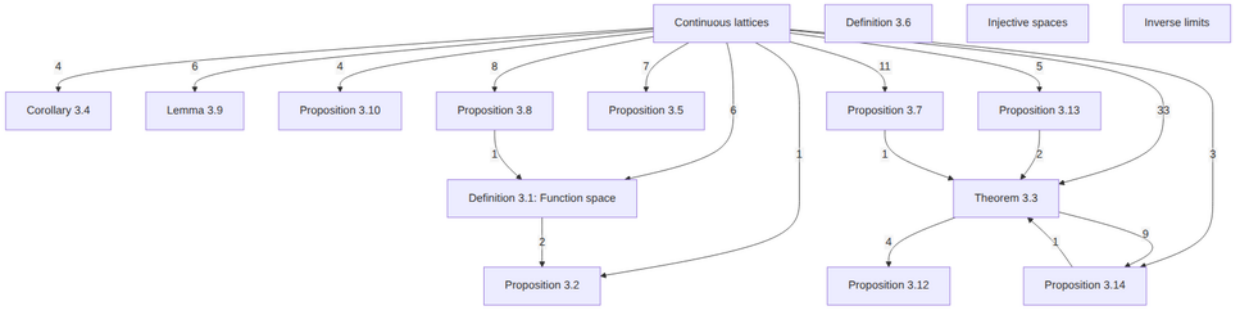

Figure 7: Function spaces.

1.4.1 Definition 3.1: Function space

3.1 Definition. For T_0-spaces X and Y we let $[X \to Y]$ be the *space of all continuous functions* $f : X \to Y$ endowed with the product topology, sometimes called the topology of pointwise convergence. This topology has as a subbase sets of the form:

$$\{f : f(x) \in U\}$$

where $x \in X$ and $U \subseteq Y$ is open.

The pointwise aspect of the topology is immediately apparent in the partial ordering.

1.4.3 Theorem 3.3

3.3 Theorem. If D and D' are continuous lattices, then so is $[D \to D']$ under the induced partial ordering with the lattice topology agreeing with the product topology.

Proof: The argument is "pointwise." Thus, the constant function with value $\perp \in D'$ is obviously continuous and is the $\perp$ of $[D \to D']$ by 3.2. Since by 2.7 the lattice operation $\sqcup$ on D' is continuous, then if $f, g \in [D \to D']$ the composition $f \sqcup g$, defined by

$$(f \sqcup g)(x) = f(x) \sqcup g(x)$$

for all $x \in D$, is also continuous and represents the lub of f, g in $[D \to D']$. (The same arguments apply to $\top$ and $\sqcap$, so $[D \to D']$ is at least a lattice.) To show that $[D \to D']$ is complete it is sufficient now to show that lubs of directed subsets exist. So let $\mathcal{F} \subseteq [D \to D']$ be directed. Define a function from D into D' by the equation:

$$(\bigsqcup \mathcal{F})(x) = \bigsqcup \{f(x) : f \in \mathcal{F}\},$$

for all $x \in D$. If we can show that $\bigsqcup \mathcal{F}$ is continuous, then being in $[D \to D']$ it has to be the lub. Consider $U \subseteq D'$, an open subset. Taking the inverse image and remembering that $\mathcal{F}$ is directed, we find:

$$\{x : (\bigsqcup \mathcal{F})(x) \in U = \bigcup x : f(x) \in U : f \in \mathcal{F}\}.$$

This is an open set, and so $\bigsqcup \mathcal{F}$ is indeed continuous. (Warning: the infinite $\sqcap \mathcal{F}$ are not in general computed pointwise; however, it is easy to extend the above argument to show that arbitrary $\bigsqcup \mathcal{F}$ are.)

To show that $[D \to D']$ is continuous, we establish first that for $f \in [D \to D']$

$$f = \bigsqcup \overrightarrow{e}[e, \{e'\} : e' \ll f(e)\},$$

where e ranges over D and e' over D', and where the function $\overrightarrow{e}[e, e']$ is defined by:

$$\overrightarrow{e}[e, e'](x) = \begin{cases} e' & \text{if } e \ll x, \\ \perp & \text{if not,} \end{cases}$$

for all $x \in D$. Call the function on the right f'. Calculate:

$$f'(x) = \bigsqcup \overrightarrow{e}[e, e'](x) : e' \ll f(e)$$

$$= \bigsqcup \{e' : \exists e \ll x \; [e' \ll f(e)]\}$$

$$= \bigsqcup \{e' : e' \ll f(x) = f(x)\}.$$

With the equation for f proved, note next that for all $g \in [D \to D']$, $e' \ll g(e)$ implies $\overrightarrow{e}[e, e'] \sqsubseteq g$ by an easy pointwise argument. If we let $V = \{g : e' \ll g(e)\}$, we see then that V is open in the product topology and that $\overrightarrow{e}[e, e'] \sqsubseteq \sqcap V$. We may then conclude that $f = \bigsqcup \{\sqcap V : f \in V\}$, which proves both that $[D \to D']$ is a continuous lattice and that the two topologies agree by the remark following 2.4. □

The above theorem might possibly be generalized to $[X \to D]$ where X is merely a T_0-space, but I was unable to see the argument. In any case we are mostly interested in the continuous lattices. Note as a consequence of our proof:

1.4.4 Corollary 3.4

3.4 Corollary. For continuous lattices D and D', the evaluation map:

$$\mathrm{eval} : [D \to D'] \times D \to D'$$

is continuous.

Proof: Here $\mathrm{eval}(f, x) = f(x)$. With f fixed, this is obviously continuous. With x fixed, we proved the continuity above with our calculation of $\bigsqcup \mathcal{F}$ in view of 2.5. Hence applying 5.3 and 2.6, we conclude that eval is jointly continuous. □

This result gives only one example of the masses of continuous functions that are available on continuous lattices. As another fundamental example we have:

corollary_3_4.lean

1.4.5 Proposition 3.5

3.5 Proposition. For continuous lattices D, D', and D'', the map of functional abstraction:

$$\text{lambda} : [[D \times D'] \to D''] \to [D \to [D' \to D'']]$$

is continuous.

Proof: Here lambda is defined by:

$$\mathrm{lambda}(f)(x)(y) = f(x,y)$$

where $f \in [[D \times D'] \to D'']$ and $x \in D$ and $y \in D'$. What is particularly interesting here is that by virtue of 3.3 we are making use of $[D \to [D' \to D'']]$ as a continuous lattice. The principle being stated here can be formulated more broadly in this way:

> If an expression $\mathcal{E}(x,y,z,\dots)$ is continuous in all its variables $x,y,z,\dots$ with values in D' as x ranges in D, then the expression
>
> $$\lambda x : D.\mathcal{E}(x,y,z,\dots)$$
>
> with values in $[D \to D']$ is continuous in the remaining variables $y,z,\dots$.

The λ-notation is a notation for functions, where in the above the variable after the λ is the *argument* and the expression after the . is the *value* (as a function of the argument). Thus we could write:

$$\mathrm{lambda} = \lambda f : [[D \times D'] \to D''].\lambda x : D.\lambda y : D'.f(x,y),$$

and, because $f(x,y)$ is continuous in f, x, and y, our conclusion follows. But often it is more readable not to write equations between functions but rather equations between values for definitional purposes.

The proof of the principle is easy. For let the variable y, say range over D'' and let $S \subseteq D''$ be a directed subset. Then

$$\lambda x : D.\mathcal{E}(x,\bigsqcup S,z,\dots) = \lambda x : D.\bigsqcup \mathcal{E}(x,y,z,\dots) : y \in S \quad = \bigsqcup \lambda x : D.\mathcal{E}(x,y,z,\dots) : y \in S,$$

because the lubs of functions are computed pointwise. □

We need not enumerate the many corollaries that follow easily now from this result. We mention, however, that composition $f \circ g$ of functions (on continuous lattices) is continuous in the two function variables, where we write

$$(f \circ g)(x) = f(g(x)).$$

1.4.6 Retractions and extensions

What will be useful will be to return at this point to a discussion of the injective properties of continuous lattices. If one continuous lattice is a subspace of another it is of course a retract. This relationship between spaces can be given by a pair of continuous maps

$$i : D \to D' \quad \text{and} \quad j : D' \to D,$$

where

$$j \circ i = \mathrm{id}_D = \lambda x : D.x.$$

The composition $i \circ j : D' \to i(D)$ is the retraction onto the subspace corresponding to D under i. Now if we have a diagram:

$$D \underset{j}{\overset{i}{\rightleftarrows}} D' f \searrow \qquad \swarrow \tilde{f} = f \circ j D''$$

the given continuous f is at once extendable from D to D' by the obvious definition of $\tilde{f}$. This $\tilde{f}$ is not the $\bar{f}$ used in the proof of 2.11, and it will be well to sort out the connections. On one side note that if f' is any function which extends f, then we have $f = f' \circ i$. But this implies

$$\tilde{f} = f \circ j = f' \circ i \circ j,$$

which shows that $\tilde{f}$ is a "degraded" version of f'. There is one situation where this type of degrading is especially nice.

1.4.7 Definition 3.6

3.6 Definition. A continuous lattice D is said to be a *projection* of a continuous lattice D' iff there are a pair of continuous maps

$$i : D \to D' \quad \text{and} \quad j : D' \to D$$

such that not only

$$j \circ i = \mathrm{id}_D,$$

but also

$$i \circ j \sqsubseteq \mathrm{id}_{D'}.$$

Thus, in case our retraction is a projection, we have $\tilde{f} \sqsubseteq f'$, which means that $\tilde{f}$ is the *minimal* extension of $f \in [D \to D'']$ to a function in $[D' \to D'']$. We will discuss the nature of $\tilde{f}$ in a moment. But before we do we pause to remark that the correspondence $f \rightsquigarrow \tilde{f}$ is *continuous*, and this fact is easily extended.

1.4.8 Proposition 3.7

3.7 Proposition. Suppose the two pairs of maps

$$i_n : D_n \to D'_n \quad \text{and} \quad j_n : D'_n \to D_n$$

for $n = 0, 1$ make D_n a retraction (projection) of D'_n. Then $[D_0 \to D_1]$ is also a retraction (projection) of $[D'_0 \to D'_1]$ by means of the pair of maps:

$$\vec{i}(f) = i_1 \circ f \circ j_0 \text{ , and}$$

$$\vec{j}(f') = j_1 \circ f' \circ i_0 \text{ ,}$$

where $f \in [D_0 \to D_1]$ and $f' \in [D'_0 \to D'_1]$. □

Returning now to $\bar{f}$ we can prove:

1.4.9 Proposition 3.8

3.8 Proposition. If D is a continuous lattice and $e : X \to Y$ a subspace embedding, then for each $f : X \to D$, the function $\bar{f} : Y \to D$ given by the formula

$$\bar{f}(y) = \bigsqcap\{\sqcap f(x) : e(x) \in U : y \in U\},$$

where U ranges over open subsets of Y and x over X, is the maximal extension of f to a function in the partially ordered set $[Y \to D]$.

Proof: We are saying that $\bar{f}$ is the maximal solution to the equation

$$f = \bar{f} \circ e.$$

We already know it is a solution, so let f' be any other. We have

$$f'(y) = \bigsqcap \sqcap f'(z) : z \in U : y \in U \quad \sqsubseteq \bigsqcap \sqcap f'(z) : z \in e(X) \cap U : y \in U = \bigsqcap \sqcap f'(e(x)) : e(x) \in U : y \in U \quad = \bigsqcap\{\sqcap$$

which establishes that $f' \sqsubseteq \bar{f}$. □

By the same argument we could show that $\bar{f}$ is the maximal solution of $\bar{f} \circ e \sqsubseteq f$. An interesting question is whether the correspondence $f \rightsquigarrow \bar{f}$ is continuous. I very much doubt it, but at this moment a counterexample escapes me. It is clear that the correspondence is monotonic, for if $f \sqsubseteq g$, then the formula of 3.8 shows that $\bar{f} \sqsubseteq \bar{g}$. This gives us a neat argument for the previous remark: if $g \circ e \sqsubseteq f$, then

$$\overline{g \circ e} \sqsubseteq \bar{f}.$$

But $g \circ e = \overline{g \circ e} \circ e$, so by 3.8, $g \sqsubseteq \overline{g \circ e}$, and $\bar{f}$ is thus maximal.

In the case that the range spaces are being extended, the following lemma relating the extensions will be very useful when we consider inverse limits.

1.4.10 Lemma 3.9

3.9 Lemma. Consider the diagram:

$$X \xrightarrow{e} Y \quad f\big\downarrow \qquad g \searrow \quad \bar{f} \swarrow \qquad \downarrow \bar{g}D \xrightarrow[j]{i} D'$$

where the upper row is a subspace embedding and the lower is a projection. If the given functions f and g are extended to $\bar{f}$ and $\bar{g}$ as in 3.8, and if $f = j \circ g$, then $\bar{f} = j \circ \bar{g}$ also.

Proof: $\bar{f}$ and $\bar{g}$ are maximal solutions of $f = \bar{f} \circ e$ and $g = \bar{g} \circ e$. Therefore since

$$f = j \circ g = j \circ \bar{g} \circ e,$$

we see that

$$j \circ \bar{g} \sqsubseteq \bar{f}.$$

Note also that

$$i \circ \bar{f} \circ e = i \circ f = i \circ j \circ g \sqsubseteq g,$$

and so by the remark following 3.8, we have

$$i \circ \bar{f} \sqsubseteq \bar{g}.$$

Therefore

$$\bar{f} = j \circ i \circ \bar{f} \sqsubseteq j \circ \bar{g},$$

which proves the equality. □

Whether this lemma is true for retractions in any form, I do not know. My proof seems to require the stronger projection relationship. I suspect there may be difficulties. In general projections are better behaved than retractions. By the way the word projection seems to be properly used in 3.6, for the projection $j : D \times D' \to D$ of the Cartesian product of two continuous lattices onto the first factor *is* a projection with partial inverse $i : D \to D \times D'$ defined by

$$i(x) = (x, \bot)$$

for $x \in D$.

variable {X Y D D' : Type*} [TopologicalSpace X] [TopologicalSpace Y]
  [CompleteLattice D] [CompleteLattice D']

/-- **Scott 1972, Lemma 3.9.** With `e : X → Y` a subspace embedding and `i, j : D ⇄
    D'` a
projection on the range, if continuous `f : X → D` and `g : X → D'` satisfy `f = j ∘ g
    `, then the
maximal extensions (Proposition 3.8) satisfy `f = j ∘ g`.

The proof is Scott's, recast through the faithful `scottExtend`:
* `j ∘ g ⊑ f`: `j ∘ g` is a continuous solution of `(j ∘ g) ∘ e = j ∘ g = f`, so
    maximality of
  `f` (`scottExtend_maximal`) gives the bound;
* `i ∘ f ⊑ g`: `(i ∘ f) ∘ e = i ∘ f = i ∘ j ∘ g ⊑ g` (since `i ∘ j ⊑ id`), so the *sub
    *-solution
  maximality of `g` (`scottExtend_maximal_le`, the remark after 3.8) gives the bound;
* combining: `f = j ∘ i ∘ f ⊑ j ∘ g ⊑ f` (using `j ∘ i = id` and monotonicity of `j`).

1.4.11 Proposition 3.10

3.10 Proposition. If the continuous lattice D is a projection of the continuous lattice D' via the pair of maps i, j; then for all $S \subseteq D$ and all $x, y \in D$ we have:

(i) $i(\bigsqcup S) = \bigsqcup\{i(x) : x \in S\}$,

(ii) $i(x) = i(y)$ implies $x = y$,

(iii) $x \ll y$ implies $i(x) \ll i(y)$.

Conversely, if a map $i : D \to D'$ satisfies (i)–(iii), then there exists a continuous $j : D' \to D$ making D a projection of D', and in fact j is uniquely determined by:

(iv) $j(x') = \bigsqcup\{x \in D : i(x) \sqsubseteq x'\}$

for all $x' \in D'$.

Proof: Equation (i) holds for directed $S \subseteq D$ because i is continuous. To have it hold for arbitrary S it is only necessary to check it for finite sets, because every lub is the directed lub of finite sublubs. (The last word of that sentence is an unfortunate accident.) Further, to check the equation for finite sets it is enough to check it for the empty set and for two element sets. Thus, $i(\bot) = \bot$, because $j(i(\bot)) = \bot$ and since $\bot \sqsubseteq i(\bot)$,

$$j(\bot) \sqsubseteq j(i(\bot)) = \bot,$$

so $j(\bot) = \bot$. Whence $i(\bot) = i(j(\bot)) \sqsubseteq \bot$. Next $i(x \sqcup y) = i(x) \sqcup i(y)$, because first

$$i(x) \sqcup i(y) \sqsubseteq i(x \sqcup y)$$

by monotonicity. Then note that

$$i(x) \sqsubseteq i(x) \sqcup i(y)$$

and so

$$x = j(i(x)) \sqsubseteq j(i(x) \sqcup i(y)).$$

Similarly

$$y \sqsubseteq j(i(x) \sqcup i(y)),$$

whence

$$x \sqcup y \sqsubseteq j(i(x) \sqcup i(y)).$$

But then

$$i(x \sqcup y) \sqsubseteq i(j(i(x) \sqcup i(y))) \sqsubseteq i(x) \sqcup i(y),$$

which completes the argument for equation (i).

Condition (ii) is obvious. For (iii) we argue as follows. Assume $x \ll y$. Since D' is continuous we can write:

$$i(y) = \bigsqcup\{z' \in D' : z' \ll i(y)\},$$

and conclude by the continuity of j that:

$$y = j(i(y)) = \bigsqcup j(z') : z' \ll i(y).$$

But $x \ll y$, so $x \ll j(z')$ for some $z' \ll i(y)$. Now $x \sqsubseteq j(z')$ follows; therefore $i(x) \sqsubseteq i(j(z')) \sqsubseteq z'$. Thus $i(x) \ll i(y)$.

Turning now to the converse, assume of the map i that it satisfies (i)–(iii). Compute:

$$i(j(x')) = \bigsqcup i(x) : i(x) \sqsubseteq x' \sqsubseteq x'.$$

This is correct because i is continuous and the set $\{x : i(x) \sqsubseteq x'\}$ is directed in view of condition (i). Thus $i \circ j \sqsubseteq \mathrm{id}_{D'}$. Note that by virtue of (i) and (ii) it is the case that

$$i(x) \sqsubseteq i(y) \text{ implies } x \sqsubseteq y.$$

(The reason is that $x \sqsubseteq y$ is equivalent to $x \sqcup y = y$.) This remark allows us to compute:

$$\begin{aligned} j(i(y)) &= \bigsqcup\{x : i(x) \sqsubseteq i(y)\} \\ &= \bigsqcup\{x : x \sqsubseteq y = y\}. \end{aligned}$$

Hence, $j \circ i = \mathrm{id}_D$. It remains to show that j is continuous. Suppose $S' \subseteq D'$ is directed. Since j is by definition monotonic, it is sufficient to prove that

$$j(\bigsqcup S') \sqsubseteq \bigsqcup j(x') : x' \in S'.$$

Now

$$j(\bigsqcup S') = \bigsqcup\{x : i(x) \sqsubseteq \bigsqcup S'\},$$

so suppose $i(x) \sqsubseteq \bigsqcup S'$. Let $z \ll x$; whence $i(z) \ll i(x)$. Thus $i(z) \ll x'$ for some $x' \in S'$, and therefore $i(z) \sqsubseteq x'$. We obtain then $z \sqsubseteq j(x')$, which means that

$$z \sqsubseteq \bigsqcup j(x') : x' \in S'$$

holds for all $z \ll x$. By the continuity of D we conclude

$$x \sqsubseteq \bigsqcup j(x') : x' \in S'$$

holds for all x with $i(x) \sqsubseteq \bigsqcup S'$. The desired result follows. □

As a corollary of 3.10 we can easily see which *subspaces* of a continuous lattice D' are projections of it. Such a subspace $D \subseteq D'$ must first be closed under $\bigsqcup$. That is, if $S \subseteq D$, then $\bigsqcup S \in D$ for

all S, where the lub is taken in the sense of D'. The identity map on D will then satisfy (i) and (ii). But this is not enough, since we would not know that D is a continuous lattice, nor whether (iii) holds. The following additional condition would be sufficient, if assumed for all $y \in D$:

$$y = \bigsqcup\{x \in D : x \ll y\},$$

where $\ll$ is taken in the sense of D'. This implies that

$$y = \bigsqcup\{\sqcap(D \cap U) : y \in U\}$$

where U ranges over the open subsets of D' and where the $\sqcap$ is taken in the sense of D. This condition makes the subspace topology the same as the lattice topology on D and besides makes D continuous, which is just what we need. (Another way to put it is that whenever $z \ll y$, where $y \in D$ but $z \in D'$, then $z \sqsubseteq x \ll y$, for some $x \in D$.)

It seems a bit troublesome to characterize in a simple way just which maps $j : D' \to D$ are projections. (Other than saying outright that the map $i : D \to D'$ such that for all $x \in D$:

$$i(x) = \sqcap\{x' \in D' : x \sqsubseteq j(x')\}$$

is the continuous partial inverse to j.) But we can say very easily which continuous maps $j : D' \to D'$ are projections onto *subspaces*; namely, we must have

$$j = j \circ j \sqsubseteq \mathrm{id}.$$

The subspace in question then is:

$$D = \{x \in D' : j(x) = x\}.$$

This non-empty subspace is the exact range of j and is closed under $\bigsqcup$. Let $y \in D$. Then if $x' \ll y$ in D', we find $j(x') \sqsubseteq x' \ll y$. Thus since

$$y = \bigsqcup\{x' \in D' : x' \ll y\},$$

we see that

$$y = j(y) = \bigsqcup\{j(x') : x' \ll y\}.$$

But each $j(x') \in D$, so $y = \bigsqcup\{x \in D : x \ll y\}$, as desired.

The foregoing discussion suggests looking more closely at the space of all projections of a continuous lattice since they are so easily characterized.

1.4.12 Definition 3.11: Projection space

3.11 Definition. Given a continuous lattice D, we let the space of projections be denoted by:

$$J_D = j \in [D \to \{D] : j = j \circ j \sqsubseteq \mathrm{id}\}.$$

1.4.13 Proposition 3.12

3.12 Proposition. For a continuous lattice D the space J_D of projections forms a complete lattice as a $\bigsqcup$-closed subspace of $[D \to D]$.

Proof: The constant function $\bot \in J_D$ obviously, so J_D contains $\bigsqcup \emptyset$. Suppose $j, k \in J_D$. We wish to show that $j \sqcup k \in J_D$. Compute:

$$(j \sqcup k)((j \sqcup k)(x)) = j(j(x) \sqcup k(x)) \sqcup k(j(x) \sqcup k(x)).$$

But note:

$$j(x) \sqsubseteq j(j(x)) \sqsubseteq j(j(x) \sqcup k(x)) \sqsubseteq j(x),$$

because $j(x) \sqcup k(x) \sqsubseteq x$. Similarly for $k(x)$. Therefore, we find that $(j \sqcup k) \circ (j \sqcup k) = j \sqcup k \sqsubseteq \mathrm{id}$.

Suppose finally that $S \subseteq J_D$ is directed. We wish to show that $\bigsqcup S \in J_D$. Clearly $\bigsqcup S \sqsubseteq \mathrm{id}$, so compute by continuity of $\circ$:

$$\bigsqcup S \circ \bigsqcup S = \bigsqcup \{j \circ j : j \in S\} = \bigsqcup \{j : j \in S\} = \bigsqcup S.$$

It follows that J_D is $\bigsqcup$-closed and hence is a complete lattice. $\square$

The significance of the above result becomes clearer if we consider the connection between projections and subspaces. Let us write:

$$D(j) = \{x \in D : j(x) = x\}.$$

For $j \in J_D$, each $D(j)$ is a projection of D onto a subspace. We show first that

$$j \sqsubseteq k \quad \text{iff} \quad D(j) \subseteq D(k).$$

Because if $j \sqsubseteq k$, then $j \sqsubseteq j \circ j \sqsubseteq k \circ j \sqsubseteq \mathrm{id} \circ j = j$. Therefore if $j(x) = x$, then $k(x) = k(j(x)) = j(x) = x$, which means that $D(j) \subseteq D(k)$. On the other hand, if $D(j) \subseteq D(k)$, then since $j(D) \subseteq D(j)$, we see that $k \circ j = j$, and so $j \sqsubseteq k \circ \mathrm{id} = k$. Hence J_D is isomorphic to the partially ordered set of subspaces of D that are projections. We thus conclude that these subspaces form a lattice. In fact, it is easy to show that

$$D(j \sqcup k) = x \sqcup \{y : x \in D(j)\}, y \in D(k).$$

Similarly, if S is a directed set of J_D, then $D(\bigsqcup S)$ is the $\bigsqcup$-closure in D of the subset:

$$\{\bigsqcup D(j) : j \in S.\}$$

These are not very deep facts, but their proofs were very much facilitated by the introduction of J_D and the utilization of the lattice structure of $[D \to D]$. Along the same line we can define for $j, k \in J_D$ a function $(j \to k) \in [D \to D] \to [D \to D]$ by the equation

$$(j \to k)(f) = k \circ f \circ j.$$

It is very easy to show that $(j \to k) \in J_{[D \to D]}$, that $(j \to k)$ is continuous in j and k, and that $[D \to D](j \to k)$ is isomorphic to $[D(j) \to D(k)]$. There are many other interesting operations on projections corresponding to other constructs besides these. And, just as with $(j \to k)$, the operations are continuous. This makes it possible to prove existence theorems about subspaces by using results like the fixed-point theorem for continuous functions. It would be even nicer if J_D turns out to be a continuous lattice itself, but as far as I can tell this is not likely to be the case.

Before we turn to the iterated function-space construction by inverse limits, there are a couple of other connections between spaces and function spaces that are useful to know.

1.4.14 Proposition 3.13

3.13 Proposition. Every continuous lattice D is a projection of its function space $[D \to D]$.

Proof: Consider the following pair of mappings $\mathrm{con} : D \to [D \to D]$ and $\mathrm{min} : [D \to D] \to D$ where

$$\mathrm{con}(x)(y) = x$$

and

$$\mathrm{min}(f) = f(\bot)$$

for all $x, y \in D$ and $f \in [D \to D]$. They are obviously continuous. The map con matches every element of D with the corresponding *constant* function in $[D \to D]$. The map min associates to every function in $[D \to D]$ its *minimum* value in the partial ordering. The proof that this pair forms a projection is trivial. □

The pair $\mathrm{con}, \mathrm{min}$ are not the only pair for making D a projection of $[D \to D]$. The following pair of maps were suggested by David Park:

$$\lambda x.\vec{e}[t, x] \quad \text{and} \quad \lambda f.f(t),$$

where x ranges over D, and f over $[D \to D]$, and where t is a fixed *isolated* element of D (that is, $t \ll t$ holds). The pair con and min will result if we set $t = \bot$. (Note that the expression $\vec{e}[t, x]$, though continuous in x, is not continuous—or even monotonic—in the variable t.) A lattice may very well possess a large number of isolated

elements, whence a large number of projections. And furthermore this is the only way the function $j = \lambda f.f(t)$ can be a projection. For assume the existence of an inverse $i : D \to [D \to D]$ satisfying the proper conditions. Then it would be the case that

$$i(x)(t) = x$$

and

$$i(f(t))(y) \sqsubseteq f(y)$$

for all $x, y \in D$ and all $f \in [D \to D]$. We can prove for all $u \in D$, if $t \not\sqsubseteq u$, then

$$i(x)(u) = \bot$$

by substituting $\vec{e}[v, x]$ for f in the second equation above, where v is chosen so that $v \ll t$ but not $v \ll u$. But then note that

$$i(x)(t) = \bigsqcup\{i(x)(u) : u \ll t\}.$$

If not $t \ll t$, then $u \ll t$ implies $t \not\sqsubseteq u$, which leads to absurdity. Hence t must be isolated, and, as we noted earlier, the function i is uniquely determined as being the one we already knew. Aside from these pairs of projections one could obtain others by combinations with automorphisms. I was unable to determine whether there are further pairs of an essentially different nature.

The topic of projections in these spaces is rather interesting since one has in a way more freedom in T_0-spaces (particularly in injective spaces) than in ordinary spaces for defining functions. As another example, consider the Cartesian square $D \times D$. Aside from the two obvious projections onto D, there is also the "diagonal" system given by the pair:

$$\lambda x.(x, x) \qquad \text{and} \qquad \lambda(x, y).x \sqcap y$$

We shall note in the next section how the choice of an initial projection effects the construction of an inverse limit.

The projections are not the only useful functions in $[D \to D] \to D$. As a final example of what can be done in function spaces we mention the fixed-point operator.

1.4.15 Proposition 3.14

3.14 Proposition. *For a continuous lattice D there is a uniquely determined continuous mapping*

$$\mathrm{fix} : [D \to D] \to D$$

where for all $f \in [D \to D]$ and $x \in D$

$$f(\mathrm{fix}(f)) = \mathrm{fix}(f)$$

and whenever $f(x) \sqsubseteq x$, then $\mathrm{fix}(f) \sqsubseteq x$.
and whenever $f(x) \sqsubseteq x$, then

$$\mathrm{fix}(f) \sqsubseteq x.$$

Proof: The proof of the existence of minimal fixed points in complete lattices is well known, as was mentioned in the proof of 2.10.

To establish the continuity, it is sufficient to remark that since all functions $f \in [D \to D]$ are continuous, we have

$$\mathrm{fix}(f) = \bigsqcup_{n=0}^{\infty} f^n(\bot),$$

where $f^n(x) = f(f(\ldots f(x)\ldots))$ (n times). Thus fix is the point-wise lub of continuous functions on $[D \to D]$ and is thus itself continuous. □

1.5 Inverse limits

By an *inverse system of spaces* we understand as usual a sequence

$$\langle X_n, j_n \rangle_{n=0}^{\infty}$$

of T_0-spaces and continuous maps $j_n : X_{n+1} \to X_n$. The space X_∞, called the *inverse limit* of the sequence, is constructed in the familiar way as that subspace of the product space consisting of exactly those infinite sequences

$$x = \langle x_n \rangle_{n=0}^{\infty},$$

where for each n we have $x_n \in X_n$, and

$$j_n(x_{n+1}) = x_n.$$

The space X_∞ is given the product topology, and the maps $j_{\infty\{n} : X_\infty \to X_n\}$ such that

$$j_{\infty n}(x) = x_n$$

are of course continous and satisfy the recursion equation:

$$j_{\infty n} = j_n \circ j_{\infty(n+1)}.$$

Besides this we have the expected extension property for any system of continuous maps

$$f_n : Y \to X_n$$

where for each n

$$f_n = j_n \circ f_{n+1}.$$

Because, we can define

$$\{f_\infty : Y \to X_\infty\}$$

by the equation

$$f_\infty(y) = \langle f_n(y) \rangle_{n=0}^{\infty}$$

for all $y \in Y$; whence

$$f_n = j_{\infty n} \circ f_\infty$$

holds. So much for a review of inverse limits. In this paper our interest will center on rather special inverse systems and their limits.

1.5.13 Proposition 4.1

4.1 Proposition. Let $\langle D_n, j_n \rangle_{n=0}^{\infty}$ be an inverse system of continuous lattices where each $j_n : D_{n+1} \to D_n$ is a projection. Then the inverse limit space D_∞ is also a continuous lattice.

Proof: We need only show that D_∞ as a T_0-space is injective. So suppose $\{f_\infty : X \to D_\infty\}$ is given and $X \subseteq Y$. Define $f_n : X \to D_n$ by $f_n = j_{\infty n} \circ f_\infty$. Let $\bar{f} * n : Y \to D_n$ be the maximal extension of f_n according to 3.8. Now we can see the point of Lemma 3.9: by this construction we guarantee that $\bar{f}n = j_n \circ \bar{f}n + 1$. Hence the required $\bar{f} * \infty : Y \to D_\infty$ exists. □

I do not know at the time of writing whether this theorem on inverse limits of continuous lattices extends to sequences where, say, the j_n are only retractions. Fortunately, sufficiently many projections exist to make this construction useful. Note that by reference to the product space construction of D_∞, its lattice ordering is given simply by the relation:

$$x \sqsubseteq y \quad \text{iff} \quad x_n \sqsubseteq y_n \text{ for all } n.$$

1.5.14 Proposition 4.2

4.2 Proposition. Let $\langle D_n, j_n\rangle_{n=0}^{\infty}$ and D_∞ be as in 4.1. Then the maps $j_{\infty\{n} : D_\infty \to D_n\}$ are projections.

Proof: The projections $j_n : D_{n+1} \to D_n$, as we know, have their uniquely determined inverses $i_n : D_n \to D_{n+1}$. We can define $\{i_{n\infty} : D_n \to D_\infty\}$ by the equation:

$$i_{n\infty}(x) = \langle y_m\rangle_{m=0}^{\infty}$$

where

$$y_m = \begin{cases} j_m(y_{m+1}) & \text{if } m < n, \\ x & \text{if } m = n, \\ i_m(y_{m-1}) & \text{if } m > n. \end{cases}$$

The proof that $i_{n\infty}$ and $j_{\infty n}$ form a projection is now an easy computation. □

One should note also the recursion equation:

$$i_{n\infty} = i_{(n+1)\infty} \circ i_n.$$

These maps also make it possible to state this useful equation:

$$x = \bigsqcup_{n=0}^{\infty} i_{n\infty}(x_n),$$

where $x \in D_\infty$. It is easy to check that this is a monotone lub, and so we can say each $x \in D_\infty$ is the limit of its projections x_n. In fact, from what we know about projections, x_n is the best possible approximation to x in the space D_n.

1.5.15 Corollary 4.3

4.3 Corollary. Let the spaces be as in 4.1 and 4.2. Let D' be any complete lattice and suppose continuous functions $f_n : D_n \to D'$ are given so that $f_n = f_{n+1} \circ i_n$. Then we can define $\{f_\infty : D_\infty \to D'\}$ by the equation:

$$f_\infty(x) = \bigsqcup_{n=0}^{\infty} f_n(x_n)$$

for $x \in D_\infty$, and we have $f_n = f_\infty \circ i_{n\infty}$. $\square$

The import of this last result is that within the category of complete lattices, the space D_∞ is not only the inverse limit of the D_n, but it is also the *direct* limit. (One system of spaces here uses the j_n as connecting maps, the other the i_n.) This is the algebraic result that lies at the heart of our main result about inverse limits of function spaces.

Turning to function spaces, let $D = D_0$ be a given continuous lattice. As we have seen in 3.13, there are many ways of making D_0 a projection of $D_1 = [D_0 \to D_0]$. Choose one such given by a pair i_0, j_0. Define recursively:

$$D_{n+1} = [D_n \to D_n]$$

and introduce the pairs i_{n+1}, j_{n+1} making D_{n+1} a projection of D_{n+2} by the method of 3.7. Specifically we shall have for $x \in D_{n+1}$ and $x' \in D_{n+2}$:

$$i_{n+1}(x) = i_n \circ x \circ j_n,$$

$$j_{n+1}(x') = j_n \circ x' \circ i_n.$$

Since these spaces are more than continuous lattices being function spaces, it is interesting to note that the maps i_n preserve function value as an algebraic operation as follows:

$$i_n(f(x)) = i_{n+1}(f)(i_n(x)),$$

where $x \in D_n$ and $f \in D_{n+1}$. Thus in passing to the limit space D_∞ something of functional application must also be preserved. The precise result shows that indeed D_∞ becomes its own function space.

Theorem 4.4 4.4 Theorem. *The inverse limit D_∞ of the recursively defined sequence $\langle D_n, j_n\rangle_{n=0}^{\infty}$ of function spaces is not only a continuous lattice, but it is also homeomorphic to its own function space $[D_\infty \to D_\infty]$.*

Proof: We can write down directly the pair of maps i_∞, j_∞ that provide the homeomorphism:

$$i_\infty(x) = \bigsqcup_{n=0}^{\infty} (i_{n\infty} \circ x_{n+1} \circ j_{\infty n}),$$

$$j_\infty(f) = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(j_{\infty n} \circ f \circ i_{n\infty}).$$

Note that these formulae are simply generalizations at the limit for the formulae we used to define i_n, j_n in the first place. Thus it is not surprising that they would provide a projection of $[D_\infty \to D_\infty]$ upon D_∞. Indeed we can compute out $j_\infty(i_\infty(x))$, noting that all the lubs are monotone and that a double monotone limit can always be replaced by a single one in view of the continuity of the operations involved, obtaining

$$j_\infty(i_\infty(x)) = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(j_{\infty n} \circ i_{n\infty} \circ x_{n+1} \circ j_{\infty n} \circ i_{n\infty}) \quad = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(x_{n+1}) = x.$$

In the converse order the calculation is only a bit more complicated. The idea is that since all the functions f are continuous and since the elements x are the limits of their approximations, then each f is actually completely determined by its

In the converse order the calculation is only a bit more complicated. The idea is that since all the functions f are continuous and since the elements x are the limits of their approximations, then each f is actually completely determined by its sequence of restrictions $j_{\infty n} \circ f \circ i_{n\infty} \in D_{n+1}$. This simple idea can be made more precise with the aid of a lemma about D_∞, which allows us in certain cases to recognize projections from limits.

Lemma 4.5 **4.5 Lemma.** Suppose for each n we have $u_{(n+1)} \in D_{n+1}$ and we let:

$$u = \bigsqcup_{n=0}^{\infty} i_{(n+1)\infty}(u_{(n+1)}).$$

Then if

$$j_{n+1}(u_{(n+2)}) = u_{(n+1)}$$

for each n, we can conclude that:

$$j_{\infty(n+1)}(u) = u_{(n+1)}.$$

Proof: If the sequence $u_{(n+1)}$ satisfies the recursion, then the limit defining u is monotonic. Therefore by continuity of projection it suffices to prove that

$$j_{\infty(n+1)}(i_{(m+1)\infty}(u_{(m+1)})) = u_{(n+1)}$$

for all $m \geqslant n$. This is obvious for $m = n$, and it can be readily proved by induction for larger m using the various recursion equations. (Properly speaking the induction is done on the quantity $(m - n)$ using both n and m as variables.) □

variable (D : ℕ → Type u) [∀ n, CompleteLattice (D n)]
variable (P : ∀ n, IsContinuousLatticeProjection (D n) (D (n + 1)))

/-- **Scott 1972, Lemma 4.5.** A criterion for recognizing projections out of the
    limit: if a
sequence `u : ∀ n, D_{n+1}` satisfies the (shifted) recursion `j_{n+1}(u_{n+2}) = u_{n
    +1}`, then the
monotone limit `u_∞ = ⋃ₙ i_{(n+1)∞}(uₙ)` has `j_{∞(n+1)}(u_∞) = uₙ`.

The proof follows Scott's argument at source lines 1316–1320.  First the defining
    family is
monotone.  Continuity of `j_{∞(n+1)}` therefore moves the projection through its
    directed
supremum.  Finally, for every `m ≥ n`, the identity
`j_{∞(n+1)}(i_{(m+1)∞}(u_m)) = u_n` is proved by induction on `m - n`, peeling one
    projection with
`projLE.succ` and then applying the recursion hypothesis `j_{m+1}(u_{m+1}) = u_m`. -/

Proof of 4.4 concluded **Proof of 4.4 concluded:** The lemma applies at once to our calculation, for we find:

$$i_\infty(j_\infty(f)) = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}\circ f\circ i_{n\infty}\circ j_{\infty n}) \quad = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n})\circ f\circ \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}).$$

Here we have just applied the continuity of f to be able to confine the lub on the right. But now by the remark following 4.2, we note the functional equation:

$$\mathrm{id} = \bigsqcup_{n=0}^{\infty}(i_{n\infty}\circ j_{\infty n}),$$

and the proof that i_∞ and j_∞ are inverse to one another is complete. □

1.5.17 The functorial form

We can explain the idea of this proof in other terms using a suggestion made to me by F. W. Lawvere. Consider the category of

We can explain the idea of this proof in other terms using a suggestion made to me by F. W. Lawvere. Consider the category of continuous lattices and projections. In that category our D_∞ is, as we have remarked, both a *direct* and an *inverse* limit. Note too that with regard to projections $[D \to D']$ is a *functor*, for we can also define $[j \to j']$ when the maps are projections. In this language our particular inverse system is defined by the recursion:

$$D_{n+1} = [D_n \to D_n] \quad \text{and} \quad j_{n+1} = [j_n \to j_n],$$

where D_0 and j_0 are given in advance. Now the function space construction is continuous in its two arguments, turning an inverse limit on the right into an inverse limit and a direct limit on the *left* also into an *inverse* limit. A repeated limit can be made into a simple limit, so we can write:

$$D_\infty = \varprojlim \langle D_n, j_n \rangle_{n=0}^{\infty} \quad = \varinjlim \langle D_n, i_n \rangle_{n=0}^{\infty}$$

and

$$[D_\infty \to D_\infty] = \varprojlim \langle [D_n \to D_n], [j_n \to j_n] \rangle_{n=0}^{\infty} \quad = \varprojlim \langle D_{n+1}, j_{n+1} \rangle_{n=0}^{\infty} = D_\infty \quad \textit{(up to isomorphism).}$$

A full checking of the details involved would not make the argument appreciably simpler over the more "element-by-element" argument I have presented. In fact, the proofs are actually the same. But thinking of the result in terms of properties of functors does seem to isolate very well the essential idea and to show how simple it is.

One must only add here a note of caution: the proper choice of category must be done with care. Thus it seems to me that the use of projections rather than arbitrary continuous maps is necessary.

Inasmuch as I have not checked all details in this form, I hope what I say is correct.

1.5.18 Application

Since we have shown $[D_\infty \to D_\infty]$ to be homeomorphic to D_∞, we can begin to regard them as the same. In particular there ought to be some function space structure to transfer to D_∞. This can be done by defining functional application for any elements $x, y \in D_\infty$ by the equation:

$$x(y) = \bigsqcup_{n=0}^{\infty} i_{n\infty}(x_{n+1}(y_n)).$$

Similarly we can define λ-abstraction on continuous expressions:

$$\lambda x.[\ldots x \ldots] = j_\infty(\lambda\{x : D_\infty\}.[\ldots x \ldots]),$$

and in this way D_∞ becomes a model for the λ-calculus of Church and Curry. The model-theoretic and proof-theoretic aspects of this result will be explained in another paper (Scott (1972)).

1.5.19 Two projections

Suppose we were to start with the least, non-trivial lattice $0 = \top, \bot$ for D_0. Now $D_1 = [0 \to 0]$ has exactly three elements and there are just two ways of defining a projection $j_0 : D_1 \to D_0$. They are illustrated in the figure:

Left projection

```
⊤  ←−− j₀ −−  [⊤,⊤]
⊥  ←−− j₀ −−  [⊥,⊤]
⊥  ←−− j₀ −−  [⊥,⊥]
```

Right projection

```
⊤  ←−− j₀ −−  [⊤,⊤]
⊤  ←−− j₀ −−  [⊥,⊤]
⊥  ←−− j₀ −−  [⊥,⊥]
```

Hence our construction gives two limit spaces D_∞ and $D' * \infty$. Are they the same? No, they are not. It can be shown, for example, that the $\top$ of $D * \infty$ is *isolated* (that is, $\top \ll \top$), while the same is not true of $D' * \infty$. More interestingly, David Park has proved that the fixed-point operator fix mentioned in 3.14 has algebraic properties in $D * \infty$ quite different from those in $D' * \infty$. By algebraic here, we of course have reference to the functional algebra embodied in the application operation $x(y)$ defined on these limit spaces. Note, by the way, that in view of our isomorphism result we can regard fix (or any other similar continuous function for that matter) as an element of $D * \infty$. This makes the "algebra" of D_∞ quite a rich field for study.

1.5.20 Embedding every space

The reader will have surely remarked that by virtue of 1.5, every T_0-space X whatsoever can be embedded as a subspace in a D_∞. Besides this all the continuous functions on X (oh, into D_∞, say) can be extended to D_∞; whence they can be regarded as *elements* of D_∞. Thus we have been able to embed not only the

topology of X into D_∞ but also all of the continuous function theory over X. So far this is only a "logical" construction. For more interesting "mathematical" results we shall have to investigate whether any useful theorems about the usual function spaces $[X \to X]$ can be obtained with the aid of D_∞. This method can easily be employed for real- or complex-valued continuous functions, though it seems more oriented toward pointwise convergence than anything else. Still, there seems to be a chance it might be useful—especially if one wished to consider continuous *operators* on function spaces.

1.5.21 Other functors

The idea of forming the limit space can also be applied to *other* functors besides $[D \to D]$. Thus instead of solving the "equation"

$$D = [D \to D]$$

as we have done with the D_∞ construction, we could also solve:

$$V = T + [V \times V] + [V + V] + [V \to V],$$

for example. Here $T = \bot, 0, 1, \top$ is the four-element lattice with 0 and 1 as incomparable elements. By $[V \times V]$ and $[V \to V]$ we understand the usual Cartesian product and function space construction. The $+$ operator, on the other hand works only in the category of lattices with $\top$ as an isolated element. It is defined so as to make:

$$\begin{array}{ccc} D + D' & \longleftarrow & D' \\ \uparrow & & \uparrow \\ D & \longleftarrow & 0 \end{array}$$

a push-out diagram, where the maps from 0 are meant to match $\bot$ with $\bot$ and $\top$ with $\top$. The point of requiring $\top$ to be isolated is that both D and D' become projections of $D + D'$. This construction, though not quite a disjoint union, has many properties in common with that operation on spaces. In particular, if we consider the category with projections as maps, the construction

$$\mathbb{F}(D) = T + [D \times D] + [D + D] + [D \to D]$$

is a *functor*. Furthermore, we can project $\mathbb{F}(T)$ onto T in an obvious way, thereby setting things up for an inverse limit construction:

$$V = \varprojlim \langle \mathbb{F}^n(T), j_n \rangle_{n=0}^{\infty}.$$

The resulting continuous lattice satisfies the desired equation up to isomorphism.

1.5.22 Subspaces of a limit

The space V constructed in the way just indicated is very rich in subspaces. To see this, consider the space $\mathcal{J}_V$ of proper projections j where $j(\top) = \top$. As in 3.12 this is a complete lattice. Now that $[V \times V]$ and $[V + V]$ and $[V \to V]$ are regarded as *subspaces* of this "universe" V itself, we can easily define *continuous operations*

$$(j \times k)\ ,\ (j + k)\ ,\ \text{and}\ (j \to k)$$

on the projections obtaining again elements of $\mathcal{J}_V$. The projections so obtained correspond to the indicated constructions of subspaces, of course. (Indeed, if we had the time and space, we could show that $\mathcal{J}_V$ becomes a very interesting category). There will be a particular

projection t corresponding to T, and reason for doing all this is to show that the existence of subspaces of V can now be established by solving equations in $\mathcal{J}_V$. For example, by the fixed-point construction we could find a $j \in \mathcal{J}_V$ such that

$$j = t + (t \times j) + ((j \times j) \to j).$$

The range of j would then be a subspace $W \subseteq V$ such that W solves the equation:

$$W = T + [T \times W] + [[W \times W] \to W].$$

And these are only a few examples: simultaneous equations are possible, and many other operators are waiting for discovery and application.

1.6 Correction

Correction (Added March, 1972). Robin Milner has pointed out to me that there is an error in the remark in the paragraph immediately preceding Proposition 2.5. I was mistaken in saying that if D is a T_0-space which becomes a complete lattice under its induced partial ordering, then every set open in the given topology is also open in the induced topology. There are many counterexamples to this statement. Let D be any complete lattice. There are two extreme T_0-topologies which will induce the given partial ordering. The smallest such topology has as a sub-base for its open sets those sets of the form:

$$\{x \in D : x \not\sqsubseteq y\}.$$

These sets are easily proved to be open in any T_0-topology which induces the partial ordering. At the other extreme consider sets of the form:

$$\{x \in D : y \sqsubseteq x.\}$$

Such sets will give a base for a T_0-topology that is the maximal topology inducing the given partial ordering. Clearly they need not be open in the induced lattice topology; in particular, they may well fail to satisfy conditions (ii) on open sets. To make the remark in question correct, we must thus suppose that the given T_0-topology is *contained within* the induced lattice topology. The equation given in the paragraph indicated will then be a sufficient condition for the two topologies to be identical.

The remark was employed in the proof of three different propositions: 2.9, 2.10, and 3.3. In the case of 2.9 one must verify that the product topology is contained within the lattice topology. This need only be done for the basis for the product topology, and for such basic open sets the result needed is obvious. In the case of proposition 2.10 the question concerns a relationship between the topologies of a space and a subspace; the spaces in question are also lattices. Note in passing that a lub in the subspace is generally *larger* in the partial ordering than the corresponding lub relative to the whole space. This puts the inequalities in the wrong direction, and so it is not immediate that a relativized open set for the subspace is open in the lattice topology of the subspace. However, in this case we can appeal to the continuous retraction. Recall that the relativized open sets of the kind that we used in the proof of 2.10 are of the form:

$$U = \{z \in D : x < z\}\ .$$

Suppose then that S is a directed set, and that using the lub in the sense of D we have

$$\bigsqcup S \in U \ .$$

Referring back to the proof of 2.10 we know that ($S' = S \subseteq D$, but $\bigsqcup S'$ is the join computed in the ambient lattice D')

$$j(\bigsqcup S') = \bigsqcup S \ ,$$

which means that

$$x < j(\bigsqcup S') \ .$$

From this it follows that

$$x < j(z), \text{ some } z \in S \ .$$

Now $j(z) = z$, and we have what we need. This argument suffices only for a special type of open sets; but these open sets form a base for the topology, and so the argument is quite general.

Turning now to the proof of theorem 2.3 we note that the topology on the function space is simply the *relativized* product topology. There is no difficulty with lubs in this case, because, as we showed in the proof of that theorem, all lubs are calculated pointwise. Thus, it is easy to verify now that the sets open in the product topology are also open in the lattice topology.

2 Datatypes as Lattices (1976)

Dependencies. Each box is one section. The arrowhead is on the section that imports. The number is how many direct imports. An arrow already implied by a longer path is left out.

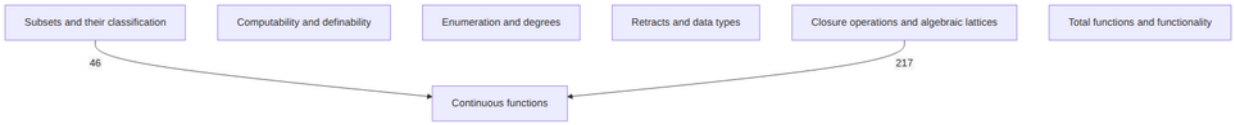

Figure 15: Datatypes as Lattices (1976).

2.1 Introduction

To the Memory of Christopher Strachey, 1916–1975

The meaning of many kinds of expressions in programming languages can be taken as elements of certain spaces of "partial" objects. In this report these spaces are modeled in one universal domain $\mathbf{P}\omega$, the set of all subsets of the integers. This domain renders the connection of this semantic theory with the ordinary theory of number theoretic (especially general recursive) functions clear and straightforward.

Investigations begun in 1969 with Christopher Strachey led to the idea that the denotations of many kinds of expressions in programming languages could be taken as elements of certain kinds of spaces of "partial" objects. As these spaces could be treated as function spaces, their structure at first seemed excessively complicated—even impossible. But then the author discovered that there were many more spaces than we had first imagined—even wanted. They could be presented as lattices (or as some prefer, semilattices), and the main technique was to employ topological ideas, in particular the notion of a continuous function. This approach and its applications have been presented in a number of publications, but that part of the foundation concerned with *computability* (in the sense of recursion theory) was never before adequately exposed. The purpose of the present paper is to provide such a foundation and to simplify the whole presentation by a de-emphasis of abstract ideas.

The main innovation in this report is to model everything within one "universal" domain $\mathbf{P}\omega = \{x \mid x \subseteq \omega\}$, the domain of all subsets of the set ω of nonnegative integers. The advantages are many: by the most elementary considerations $\mathbf{P}\omega$ is recognized to be a lattice and a topological space. In fact, $\mathbf{P}\omega$ is a *continuous lattice*, even an *algebraic lattice*, but in the beginning we do not even need to define such an "advanced" concept; we can save these ideas for an *analysis* of what has been done here in a more direct way. Next by taking the set of integers as the basis of the construction, the connection with the ordinary theory of number-theoretic (especially, general recursive) functions can be made clear and straightforward.

The model $\mathbf{P}\omega$ can be intuitively viewed as the domain of *multiple-valued* integers; what is new in the presentation is that functions are not only multiple-valued but also "multiple-argumented". This remark is given a precise sense in § 2 below, but the upshot of the idea is that multiple-valued integers are regarded as objects in themselves—possibly infinite—and as something more than just the collection of single integers contained in them. This combination of the finite with the infinite into a single domain, together with the idea that a continuous function can be reduced to its *graph* (in the end, a set of integers), makes it possible to view an $x \in \mathbf{P}\omega$ at one time as a value, at another as an argument, then as an integer, then as a function, and still later as a functional (or combinator). The "paradox" of self-application (as in $x(x)$) is solved by allowing the *same* x to be used in two *different* ways. This is done in ordinary recursion theory via Gödel numbers (as in $\{e\}(e)$), but the advantage of the present theory is that not only is the function concept the

extensional one, but it includes *arbitrary* continuous functions and not just the computable ones.

Section 1 introduces the elementary ideas on the topology of $\mathbf{P}\omega$ and the continuous functions including the fixed-point theorem. Section 2 has to do with computability and definability. The language LAMBDA is introduced as an extension of the pure λ-calculus by four arithmetical combinators; in fact, it is indicated in § 3 how the whole system could be based on *one* combinator. What is shown is that computability in $\mathbf{P}\omega$ according to the natural definition (which assumes that we already know what a recursively enumerable set of integers is) is equivalent to LAMBDA-definability. The main tool is, not surprisingly, the first recursion theorem formulated with the aid of the so-called *paradoxical combinator* $\mathbf{Y}$. The plan is hardly original, but the point is to work out what it all means in the model.

Along the way we have to show how to give every λ-term a denotation in $\mathbf{P}\omega$; the resulting principles of λ-calculus that are thereby verified are summarized in Table 1. Of these the first three, (α), (β), and (ξ), are indeed valid in the model; however, rule (η), which is a stronger version of extensionality, *fails* in the $\mathbf{P}\omega$ model. This should not be regarded as a disadvantage since the import of (η) is to suppose every object is a function. A quick construction of these special models is indicated at the end of § 5. Since $\mathbf{P}\omega$ is partially ordered by $\subseteq$, there are also laws involving this relation. Law (ξ^*) is an improvement of (ξ); while (μ) is a form of monotonicity for application.

TABLE 1

Some laws of λ-calculus

(α)	$\lambda x.\tau = \lambda y.\tau[y/x]$
(β)	$(\lambda x.\tau)(y) = \tau[y/x]$
(ξ)	$\lambda x.\tau = \lambda x.\sigma \quad \text{if} \quad \forall x.\, \tau = \sigma$
(η)	$y = \lambda x.y(x)$
(ξ^*)	$\lambda x.\tau \subseteq \lambda x.\sigma \quad \text{if} \quad \forall x.\, \tau \subseteq \sigma$
(μ)	$x \subseteq y$ and $u \subseteq v$ imply $u(x) \subseteq v(y)$

Section 3 has to do with enumeration and degrees. Gödel numbers for LAMBDA are defined in a very easy way which takes advantage of the notation of combinators. This leads to the second recursion theorem, and results on incompleteness and undecidability follow along standard lines. *Relative recursiveness* is also very easy to define in the system, and we make the tie-in with *enumeration degrees* which correspond to finitely generated combinatory subalgebras of $\mathbf{P}\omega$. Finally a theorem of Myhill and Shepherdson is interpreted as a most satisfactory completeness property for definability in the system.

Sections 4 and 5 show how a calculus of *retracts* leads to quite simple definitions of a host of useful domains (as lattices). Section 6 investigates the classification of other subsets (*nonlattices*) of $\mathbf{P}\omega$; while § 7 contrasts partial (multiple-valued) functions with total functions, and interprets various theories of functionality. Connections with category theory are mentioned.

What is demonstrated in this work is how the language LAMBDA, together with its interpretation in $\mathbf{P}\omega$, is an extremely convenient vehicle for *definitions* of computable functions on complex structures (all taken as subdomains of $\mathbf{P}\omega$). It is a "high-level" programming language for recursion theory. It is *applied* combinatory logic, which in usefulness goes far beyond anything envisioned in the standard literature. What has been shown is how many interesting predicates can be *expressed* as equations between continuous functions. What is needed next is a development of the *proof theory* of the system along the lines of the work of Milner, which incorporates the author's extension of McCarthy's rule of recursion induction to this high-level language. Then we will have a flexible and practical "mathematical" theory of computation.

2.1.1 Historical note

The paper comes out of work with Christopher Strachey begun in 1969. He treated the λ-calculus as ordinary algebra. Scott's first answer was a typed theory of function spaces, later developed as LCF by Robin Milner and his collaborators. Those function spaces, which he had met in the recursion theory of Nerode and Platek, led to the inverse-limit construction of function spaces of infinite type: models of the type-free λ-calculus, written up in Scott (1971) and Scott (1973).

Plotkin (1972) had proposed a set-theoretic model. This paper is the form of that idea in which the connection with ordinary recursion theory is immediate, because the elements are sets of integers. Scott presented it at Oberwolfach at Easter 1973, and in a shorter version at the Third Scandinavian Logic Symposium (Scott (1975)). Lectures at Kiel in July 1974 covered most of the paper; the text, without the acknowledgments or the references, appeared in Springer Lecture Notes in Mathematics, volume 499. Once the definitions had settled, the model was Plotkin's, and it was already present in the enumeration operators of Myhill and Shepherdson (1955) and Friedberg and Rogers (1959).

At the end of §2 of *Continuous lattices* (Scott (1972)) he had written that representing a continuous-function space as a computable retract "does not seem to be of too much help in proving theorems." That representation is the construction of this paper. Attributions for the separate sections are recorded on those sections.

2.2 Continuous functions

The constructions below are the enumeration of finite subsets, the pairing of natural numbers, the positive topology, the graph of a continuous function, the least fixed point, and the embedding of a continuous function.

Dependency diagram. Each box is one construction. The arrowhead is on the note that imports. The number is how many direct imports. An arrow already implied by a longer path is left out.

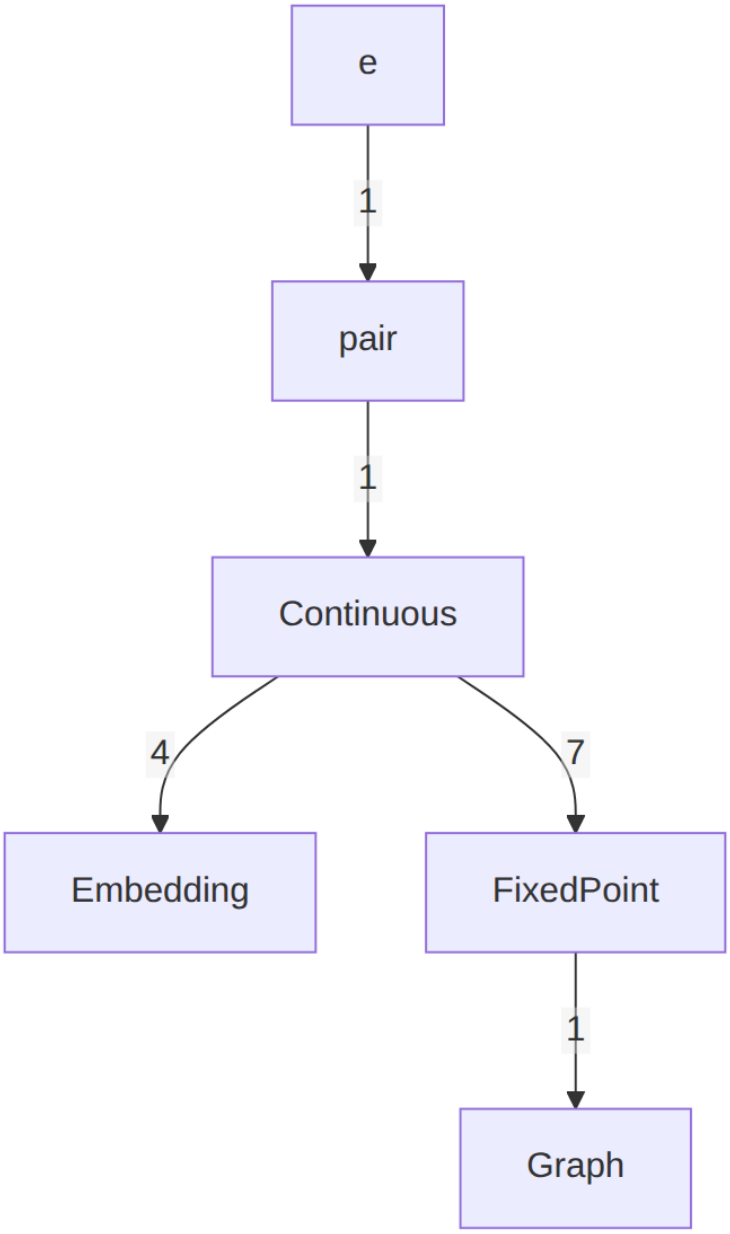

Figure 16: Continuous functions.

2.2.1 Introduction

The domain $\mathbf{P}\omega$ of all subsets of the set ω of nonnegative integers is a complete lattice under the partial ordering $\subseteq$ of set inclusion, as is well known. We use the usual symbols $\cup$, $\cap$, $\bigcup$, $\bigcap$ for the finite and infinite lattice operations of union and intersection. $\mathbf{P}\omega$ is of course also a Boolean algebra; and for complements we write

$$\sim x = \{n \mid n \notin x\}$$

where it is understood that such variables as i, j, k, l, m, n range over *integers in* ω, while u, v, w, x, y, z range over *subsets of* ω.

The domain $\mathbf{P}\omega$ can also be made into a topological space—in many ways. A common method is to match each $x \subseteq \omega$ with the corresponding characteristic function in $\{0,1\}^\omega$, and to take the induced product topology. In this way $\mathbf{P}\omega$ is a totally disconnected compact Hausdorff space homeomorphic to the Cantor "middle-third" set. This is *not* the topology we want; it is a *positive-and-negative* topology which makes the function $\sim x$ continuous. We want a weaker topology: the topology of positive "information", which has the advantage that all continuous functions possess fixed points. (The equation $x = \sim x$ is impossible.) The topology that we *do* want is exactly that appropriate to considering $\mathbf{P}\omega$ to be a continuous lattice. But all this terminology of abstract mathematics is quite unnecessary, since the required definitions can be given in very elementary terms.

To make the topology "visible", we introduce a standard enumeration $\{e_n \mid n \in \omega\}$ of all *finite* subsets of ω. Specifically we set

$$e_n = \{k_0, k_1, \cdots, k_{m-1}\},$$

provided that $k_0 < k_1 < \cdots < k_{m-1}$ and $n = \sum_{i<m} 2^{k_i}$. Thus n is the code number for e_n, and the elements of e_n are the exponents in the binary expansion of the integer n. This is a one-to-one enumeration of finite subsets, where $k \in e_n$ always implies $k < n$, the function $\max(e_n)$ is (primitive) recursive in n, and the relations $k \in e_n$, $e_n \subseteq e_m$, $e_n = e_m \cup e_k$ are all (primitive) recursive in k, m, n.

Topologically speaking the finite sets e_n are *dense* in the space $\mathbf{P}\omega$, for each $x \in \mathbf{P}\omega$ is the "limit" of its finite subsets in the sense that

$$x = \bigcup \{e_n \mid e_n \subseteq x\}.$$

To make this precise we need a rigorous definition of *open subset* of $\mathbf{P}\omega$.

Motivation Give $\{\bot, \top\}$ the weak T_0-topology with open sets $\varnothing$, $\{\top\}$, and $\{\bot, \top\}$. That is the Sierpinski space, and the product $\{\bot, \top\}^\omega$ in the product topology is $\mathbf{P}\omega$. The finite sets e_n are the basic open sets of the product. Theorem 1.1 is that observation written out in elementary terms.

On a subspace $X \subseteq \mathbf{P}\omega$ a finite set e_n need not lie in X, so continuity of $f : X \to \mathbf{P}\omega$ cannot be written by applying f to e_n. Theorem 1.5 is the substitute. Such an f is continuous exactly when it is the restriction of its extension $\bar{f}$, and for $x \in X$ that reads

$$m \in f(x) \quad \text{iff} \quad \exists e_n \subseteq x \; \forall x' \in X \; [e_n \subseteq x' \text{ implies } m \in f(x')].$$

The extension $\bar{f} : \mathbf{P}\omega \to \mathbf{P}\omega$ is continuous for an arbitrary f. It extends f precisely when f is continuous.

The fixed-point formula uses the same fact in the form Scott recorded for an increasing sequence: if $x_n \subseteq x_{n+1}$ and f is continuous, then f preserves the union of the x_n. Every fixed point lies above every iterate of $\varnothing$, so the union is the least one.

Historical note The positive topology came to Scott's attention through Nerode (1959). Continuous functionals had been studied by Kleene, Platek, and others, and Platek (1964) is where monotonicity is stressed. Graphs and application are used in the same way by Plotkin (1972) and by Rogers (1967, p. 147). The fixed-point theorem is Tarski's (1955). The extension theorem is Scott's, in the spirit of point-set topology, and it is the characterization of continuous lattices in Scott (1972). The embedding theorem is the standard one; Čech (1966) is a reference.

2.2.2 e

The powerset of the natural numbers, and the enumeration of its finite subsets by the binary code `e`. The declarations named `e_` are the facts about that code. The others are the domain, the membership tests, and the coding of finite lists and finite sets that those facts use.

Definition (basis) **DEFINITION.** A *basis* for the neighborhoods of $\mathbf{P}\omega$ consists of those sets of the form:

$$\{x \in \mathbf{P}\omega \mid e_n \subseteq x\},$$

for a given e_n. An arbitrary *open subset* is then a union of basic neighborhoods.

It is easy to prove that an open subset $U \subseteq \mathbf{P}\omega$ is just a set of "finite character"; that is, a set such that for all $x \in \mathbf{P}\omega$ we have $x \in U$ if and only if some finite subset of x also belongs to U. An alternate approach would define directly what we mean by a continuous function using the idea that such functions must preserve limits.

Definition (continuous) **DEFINITION.** A function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is *continuous* iff for all $x \in \mathbf{P}\omega$ we have:

$$f(x) = \bigcup\{f(e_n) \mid e_n \subseteq x\}.$$

Again it is an easy exercise to prove that a function is continuous in the sense of this definition iff it is continuous in the usual topological sense (namely: inverse images of open sets are open). For giving proofs it is even more convenient to have the usual ε-δ formulation of continuity.

Theorem 1.1 **THEOREM 1.1** (The characterization theorem). A function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is *continuous* iff for all $x \in \mathbf{P}\omega$ and all e_m we have:

$$e_m \subseteq f(x) \quad \text{iff} \quad \exists e_n \subseteq x.\ e_m \subseteq f(e_n).$$

Note that open sets and continuous functions have a *monotonicity property*:
whenever $x \subseteq y$ *and* $x \in U$, *then* $y \in U$; *and*
whenever $x \subseteq y$, *then* $f(x) \subseteq f(y)$.

This gives a precise expression to the "positive" character of our topology. However, note too that openness and continuity mean rather more than just monotonicity. In particular, a continuous function is completely determined by the pairs of integers n, m such that $m \in f(e_n)$, as can be seen from the definition. (Hence, there are only a continuum number of continuous functions, but more than a continuum number of monotonic functions.) This brings us to the definition of the *graph* of a continuous function.

To formulate the definition, we introduce a standard enumeration (n, m) of all pairs of integers. Specifically we set

$$(n, m) = \tfrac{1}{2}(n + m)(n + m + 1) + m.$$

This is the enumeration along the "little diagonals" going from left to right, and it produces the ordering:

$$(0,0),(1,0),(0,1),(2,0),(1,1),(0,2),(3,0),(2,1),\ldots.$$

Note that $n \leq (n,m)$ and $m \leq (n,m)$ with equality possible only in the cases of $(0,0)$ and $(1,0)$. This is a one-to-one enumeration, and the inverse functions are (primitive) recursive—but we do not require at the present any notation for them.

/-- **Scott 1976, Theorem 1.2 (iii).** Equality in (ii) iff `u` is downward
closed in the finite-set argument: `(k, m) ∈ u` and `e k ⊆ e n` imply `(n, m) ∈ u`. -/
class IsGraph (u : Pomega) : Prop where
  out : ∀ {{k m n}}, pair k m ∈ u → e k ⊆ e n → pair n m ∈ u

end DomainTheory.DataTypesAsLattices
```

Definition (graph) **DEFINITION.** The graph of a continuous function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ is defined by the equation:

$$\mathbf{graph}(f) = \{(n, m) \mid m \in f(e_n)\};$$

while the function determined by any set $u \subseteq \omega$ is defined by the equation:

$$\mathbf{fun}(u)(x) = \{m \mid \exists e_n \subseteq x.\ (n, m) \in u\}.$$

Theorem 1.2 **THEOREM 1.2** (The graph theorem). *Every continuous function is uniquely determined by its graph in the sense that:*

(i) $\mathbf{fun}(\mathbf{graph}(f)) = f$.

Conversely, every set of integers determines a continuous function and we have:

(ii) $u \subseteq \mathbf{graph}(\mathbf{fun}(u))$,

where equality holds just in case u satisfies:

(iii) *whenever $(k, m) \in u$ and $e_k \subseteq e_n$, then $(n, m) \in u$.*

Besides functions of one variable we need to consider also functions of several variables. The official definition for one variable given above can be extended simply by saying $f(x, y, \dots)$ is continuous iff it is continuous in each of $x, y, \dots$. Those familiar with the product topology can prove that for our special positive topology on $\mathbf{P}\omega$ this is equivalent to being continuous on the product space (continuous in the variables jointly). Those interested only in elementary proofs can calculate out directly from the definition (with the aid of 1.1) that continuity behaves under combinations by substitution [as in: $f(g(x, y), h(y, x, y))$].

2.2.6 FixedPoint

Dependencies. Inside FixedPoint, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Theorem 1.4 The other general fact about continuous functions that we shall use constantly concerns fixed points, whose existence can be proved using a well-known method.

THEOREM 1.4 (The fixed-point theorem). *Every continuous function $f : \mathbf{P}\omega \to \mathbf{P}\omega$ has a least fixed point given by the formula:*

$$\mathbf{fix}(f) = \bigcup\{f^n(\varnothing) \mid n \in \omega\},$$

where $\varnothing$ is the empty set and f^n is the n-fold composition of f with itself.

Actually **fix** is a *functional* with continuity properties of its own. We shall not give the required definitions here because they can be more easily derived from the construction of the model given in the next section.

For those familiar with the abstract theory of topological spaces we give in conclusion two general facts about continuous functions with values in $\mathbf{P}\omega$ which indicate the scope and generality of our method.

Theorem 1.6 **THEOREM 1.6** (The embedding theorem). *Every T_0-space X with a countable basis $\{U_n \mid n \in \omega\}$ for its topology can be embedded in $\mathbf{P}\omega$ by the continuous function $\varepsilon : X \to \mathbf{P}\omega$ defined by the equation:*

$$\varepsilon(x) = \{n \mid x \in U_n\}.$$

Technically the T_0-hypothesis is what is needed to show that ε is one-to-one. The upshot of these two theorems is that in looking for (reasonable) topological structures we can confine attention to the subspaces of $\mathbf{P}\omega$ and to continuous functions defined on *all* of $\mathbf{P}\omega$. Thus the emphasis on a single space is justified structurally. What we shall see in the remainder of this work is that the use of a single space is also justified practically because the required subspaces and functions can be *defined* in very simple ways by a natural method of equations.

2.3 Computability and definability

2.3.1 Historical note

The language LAMBDA is Scott's. Plotkin and Rogers already used graphs, application, and conversion, and the combinators they had would have defined abstraction if anyone had asked; the abstraction operation is what this section supplies. The reduction theorem and the combinator theorem are the classical ones from combinatory logic. The first recursion theorem is classical as well. The argument that Curry's combinator $\mathbf{Y}$ is the least fixed point in this model is David Park's, from an unpublished note of 1970, and it is recorded with Theorem 2.5. The equation $\mathbf{Y}(u) = u(\mathbf{Y}(u))$ is the usual calculation from (2.8). Leastness uses the pairing (n, m) and the finite sets e_l, and does not appeal to Theorem 1.4. The definition of computability and Theorem 2.6 identify the LAMBDA-definable functions with the enumeration operators.

Dependency diagram. Each box is one note that contains Lean. The arrowhead is on the note that imports. The number is how many direct imports. An arrow already implied by a longer path is left out.

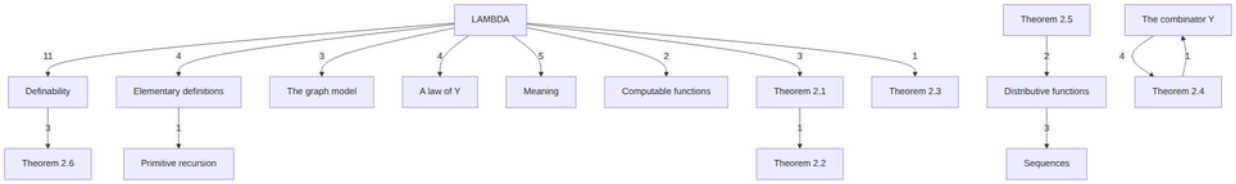

Figure 21: Historical note.

2.3.2 Meaning

The purpose of the first section was to introduce in a simple-minded way the basic notions about the topology of $\mathbf{P}\omega$ and its continuous functions. In this section we wish to present the details of a powerful language for defining *particular* functions—especially computable functions—and initiate the study of the *use* of these functions. This study is then extended in different ways in the following sections.

Before looking at the language, a short discussion of the "meaning" of the elements $x \in \mathbf{P}\omega$ will be helpful from the point of view of motivation. Now in itself $x \in \mathbf{P}\omega$ is a set, but this does not reveal its *meaning*. Actually x has no "fixed" meaning, because it can be *used* in strikingly different ways; we look for meaning here solely in terms of use. Nevertheless it is possible to give some coherent guidelines.

In the first place it is convenient to let the singleton subsets $\{n\} \in \mathbf{P}\omega$ stand for the corresponding integers. In fact, we shall enforce by convention the equation $n = \{n\}$ as a way of simplifying notation. In this way, $\omega \subseteq \mathbf{P}\omega$ as a subset. (Note that our convention conflicts with such set-theoretical equations as $5 = \{0, 1, 2, 3, 4\}$. What we have done is to abandon the usual set-theoretical conventions in favor of a slight redefinition of *set of integers* which produces a more helpful convention for present purposes.) So, if we choose, a singleton "means" a single integer. The next question is what a "large" set $x \in \mathbf{P}\omega$ could mean. Here is an answer: if we write:

$$x = \{0, 5, 17\} = 0 \cup 5 \cup 17,$$

we are thinking of x as a *multiple integer*. This is especially useful in the case of multiple-valued function where we can write:

$$f(a) = 0 \cup 5 \cup 17.$$

Then "$m \in f(a)$" can be interpreted as "m is one value of f at a." Now $a \in \mathbf{P}\omega$, too, and so it is a multiple integer also. This brings us to an important point.

A multiple integer is (often) *more* than just the (random) collection of its elements. From the definition of continuity, $m \in f(a)$ is equivalent to $m \in f(e_n)$ with $e_n \subseteq a$. We may not be able to reduce this to $m \in f(\{n\})$ with $n \in a$ without additional assumptions on f. Indeed we shall take advantage of the feature of continuous functions whereby the elements of an argument a can join in *cooperation* in determining $f(a)$. Needless to say, continuity implies that the cooperation cannot extend beyond *finite* configurations, and so we can say that a is the union (or limit) of its finite subsets. However, finitary cooperation will be found to be quite a powerful notion.

Where does this interpretation leave the empty set $\varnothing$? When we write "$f(a) = \varnothing$" we can read this as "f has no value at a", or "f is undefined at a". In this case $f(a)$ exists (as a set), but it is not "defined" as an integer. Single- (or singleton-) valued functions are "well-defined", but multiple-valued functions are rather "over-defined".

How does this interpretation fit in with monotonicity? In case $a \subseteq b$ and $m \in f(a)$, then we must have $m \in f(b)$. We can read "$a \subseteq b$" as "b is an *improvement of* a" or "b is *better-defined than* a." The point of monotonicity is that the better we define an argument, the better we define a value. "Better" does not imply "well" (that is, singleton-valuedness), and overdefinedness may well creep in. This is not the fault of the function; it is our fault for not choosing a different function.

As a subspace $\omega \subseteq \mathbf{P}\omega$ is discrete. This implies that arbitrary functions $p : \omega \to \omega$ are continuous. Note that $p : \omega \to \mathbf{P}\omega$ as well, because $\omega \subseteq \mathbf{P}\omega$. By Theorem 1.5 we can extend p continuously to $\bar{p} : \mathbf{P}\omega \to \mathbf{P}\omega$. The formula given produces this function:

$$\bar{p}(x) = \begin{cases} \bigcap\{p(n) \mid n \in \omega\} & \text{if } x = \varnothing; \\ p(n) & \text{if } x = n \in \omega; \\ \omega & \text{otherwise.} \end{cases} \tag{2.1}$$

This is a rather abrupt extension of p (the *maximal extension*); a more gradual, continuous extension (the *minimal extension*) is determined by this equation:

$$\hat{p}(x) = \bigcup\{p(n) \mid n \in x\}. \tag{2.2}$$

The same formulae work for *all* multiple-valued functions $p : \omega \to \mathbf{P}\omega$. Functions like $f = \hat{p}$ are exactly characterized as being those continuous functions $f : \mathbf{P}\omega \to \mathbf{P}\omega$ which in addition are *distributive* in the sense of these equations:

$$f(x \cup y) = f(x) \cup f(y) \quad \text{and} \quad f(\varnothing) = \varnothing.$$

The sets $\varnothing$ and ω play special roles. When we consider them as elements of $\mathbf{P}\omega$ we shall employ the notation:

$$\bot = \varnothing \quad \text{and} \quad \top = \omega$$

The element $\bot$ is the most "undefined" integer, and $\top$ is the most "overdefined". All others are in between.

One last general point on meaning: suppose $x \in \mathbf{P}\omega$ and $k \in x$. Then $k = (n, m)$ for suitable (uniquely determined) integers n and m. That is to say, every element of x can be regarded as an ordered pair; thus, x can be used as a relation. Such an operation as

$$(2.3) \quad x; y = \{(n, l) \mid \exists m.\, (n, m) \in x,\, (m, l) \in y\}$$

is then a continuous function of two variables that treats both x and y as relations. On the other hand we could define a quite different continuous function such as

$$(2.4) \quad x + y = \{n + m \mid n \in x,\, m \in y\}$$

which treats both x and y arithmetically. The only reason we shall probably never write $(x + y); x$ again is that the values of this perfectly well-defined continuous function are, for the most part, quite uninteresting. There is, however, no theoretical reason why we cannot use the same set with several different "meanings" in the same formula. Of course if we do so, it is to be expected that we will show the point of doing this in the special case. We turn now to the definition of the general language for defining all such functions.

2.3.3 LAMBDA

The syntax and semantics of the language LAMBDA are set out in Table 2. The syntax is indicated on the left, and the meanings of the combinations are shown on the right as subsets of $\mathbf{P}\omega$. This is the basic language and could have been given (less understandably) in terms of combinators (see Theorem 2.4). It is, however, a very primitive language, and we shall require many definitions before we can see why such functions as in (2.3) and (2.4) are themselves definable.

TABLE 2

The language LAMBDA

$$0 = \{0\}$$

$$x + 1 = \{n + 1 \mid n \in x\}$$

$$x - 1 = \{n \mid n + 1 \in x\}$$

$$z \supset x, y = \{n \in x \mid 0 \in z\} \cup \{m \in y \mid \exists k.\, k + 1 \in z\}$$

$$u(x) = \{m \mid \exists e_n \subseteq x.\, (n, m) \in u\}$$

$$\lambda x.\, \tau = \{(n, m) \mid m \in \tau[e_n/x]\}$$

The definition has been left somewhat informal in hopes that it will be more understandable. In the above, τ is any term of the language. LAMBDA is type-free and allows any combination to be made by substitution into the given functions. There is one primitive constant (0); there are two unary functions $(x + 1,\ x - 1)$; there is one binary function $(u(x))$ and one ternary function $(z \supset x, y)$; finally there is one variable binding operator $(\lambda x.\, \tau)$. The first three equations have obvious sense. In the fourth, $z \supset x, y$ is McCarthy's conditional expression (a test for zero). Next $u(x)$ defines *application* (u is treated as a graph and x as a set), and $\lambda x.\, \tau$ is *functional abstraction* (compare the definition of **fun**). In defining $\lambda x.\, \tau$, we use $\tau[e_n/x]$ as a shorthand for evaluating the term τ when the variable x is given the value e_n.

Note that the functions are all multiple-valued. Thus we have such a result as:

$$(2.5) \quad (6 \cup 10) + 1 = 7 \cup 11.$$

The partial character of subtraction has expression as:

$$(2.6)\quad 0 - 1 = \bot.$$

We shall see how to define $+$ and $-$ in LAMBDA later. The conditional could also have been defined by cases:

$$(2.7)\quad z \supset x, y = \begin{cases} \bot & \text{if } z = \bot; \\ x & \text{if } z = 0; \\ y & \text{if } 0 \notin z \neq \bot; \\ x \cup y & \text{if } 0 \in z \neq 0. \end{cases}$$

We say that a LAMBDA-term τ defines a function of its free variables (at least).

2.3.6 Theorem 2.3

By "model" here we of course understand the interpretation of the language where the semantics gives terms denotations in $\mathbf{P}\omega$ according to the stated definition. Through this interpretation, more properly speaking, $\mathbf{P}\omega$ becomes a model for the axioms (α), (β), (ξ). Two well-known results of the calculus of λ-conversion allow the reduction of functions of several variables to those of *one*, and the reduction of all the primitives to *combinators* (constants)—all this with the aid of the binary operation of application.

THEOREM 2.3 (The reduction theorem). *Any continuous function of k-variables can be written as*

$$f(x_0, x_1, \cdots, x_{k-1}) = u(x_0)(x_1)\cdots(x_{k-1}),$$

where u is a suitably chosen element of $\mathbf{P}\omega$.

2.3.7 Theorem 2.4

THEOREM 2.4 (The combinator theorem). *The LAMBDA-definable functions* can be generated (*from variables*) by iterated application with the aid of these six constants:

$$\mathbf{0} = 0$$

$$\mathbf{suc} = \lambda x.\, x + 1$$

$$\mathbf{pred} = \lambda x.\, x - 1$$

$$\mathbf{cond} = \lambda x \lambda y \lambda z.\, z \supset x, y$$

$$\mathbf{K} = \lambda x \lambda y.\, x$$

$$\mathbf{S} = \lambda u \lambda v \lambda x.\, u(x)(v(x))$$

But the result that makes all this model building and combinatory logic mathematically interesting concerns the so-called *paradoxical combinator* defined by the equation:

$$(2.8) \quad \mathbf{Y} = \lambda u.\, (\lambda x.\, u(x(x)))(\lambda x.\, u(x(x))).$$

2.3.9 Theorem 2.5

THEOREM 2.5 (The first recursion theorem). *If u is the graph of a continuous function f, then $\mathbf{Y}(u) = \mathbf{fix}(f)$, the least fixed point of f.*

There are two points to note here: the fixed point is LAMBDA-definable if f is; and $\mathbf{Y}$ defines a continuous operator. The word "recursion" is attached to the theorem because fixed points are employed to solve recursion equations. It would not be correct to call the fixed-point theorem (Theorem 1.4) the recursion theorem since it only shows that fixed points exist and not how they are definable in a language. The *second* recursion theorem (in Kleene's terminology) is related, but it involves Gödel numbers as introduced in § 3.

From this point on we see no need to distinguish continuous functions from elements of $\mathbf{P}\omega$; a continuous function will be *identified* with its graph. Note that u is a graph iff $u = \lambda x.\, u(x)$, which is equivalent to Theorem 1.2 (iii). For this reason (functions are graphs) we propose the name *Graph Model* for this model of the λ-calculus. (There is more to LAMBDA than just λ, however.)

The identification of functions with graphs entails that the function space of all continuous functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$ is to be identified (one-to-one) with the subspace

$$\mathbf{FUN} = \{u \mid u = \lambda x.\, u(x)\} \subseteq \mathbf{P}\omega.$$

The identification is *topological* in that the subspace topology agree with the product topology on the function space. This is the topology of pointwise convergence and is closely connected with the lattice structure on the function space which is also defined pointwise (that is, argumentwise). In the notation of λ-abstraction we can express this as the extension of the axiom of extensionality called (ξ^*) in Table 1 of the Introduction. The laws in Table 1 are not the only ones valid in the model, however. We may also note such argumentwise distribution laws as:

$$(2.9) \quad (f \cup g)(x) = f(x) \cup g(x);$$

$$(2.10) \quad (\lambda x.\, \tau) \cup (\lambda x.\, \sigma) = \lambda x.\, (\tau \cup \sigma);$$

$$(2.11) \quad (f \cap g)(x) = f(x) \cap g(x);$$

$$(2.12) \quad (\lambda x.\, \tau) \cap (\lambda x.\, \sigma) = \lambda x.\, (\tau \cap \sigma).$$

In the above f and g must be graphs. It is also true that if $\mathcal{F} \subseteq \mathbf{P}\omega$, then

$$(2.13) \quad \bigcup\{f \mid f \in \mathcal{F}\}(x) = \bigcup\{f(x) \mid f \in \mathcal{F}\},$$

but the same does not hold for $\cap$.

We state now a sequence of minor results which show why some simple functions and constants are LAMBDA-definable.

$$(2.14) \quad \bot = (\lambda x.\, x(x))(\lambda x.\, x(x));$$

$$(2.15) \quad x \cup y = (\lambda z.\, 0) \supset x, y; \quad \text{(Hint: } 0, 1 \in \lambda z.\, 0)$$

$$(2.16) \quad \top = \mathbf{Y}(\lambda x.\, 0 \cup (x + 1));$$

$$(2.17) \quad x \cap y = \mathbf{Y}(\lambda f \lambda x \lambda y.\, x \supset (y \supset 0, \bot), f(x - 1)(y - 1) + 1)(x)(y).$$

The elements $\bot$ and $\top$ are graphs, by the way, and we can characterize them as the only fixed points of the combinator $\mathbf{K}$:

$$(2.18) \quad a = \lambda x.\, a \quad \text{iff} \quad a = \bot \quad \text{or} \quad a = \top.$$

Next we use the notation $\langle x_0, x_1, \ldots, x_{n-1}\rangle$ for the function $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is defined by:

$$p(i) = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases}$$

$$(2.19)\quad \langle\rangle = \bot$$

$$(2.20)\quad \langle x\rangle = \lambda z.\, z \supset x, \bot$$

$$(2.21)\quad \langle x, y\rangle = \lambda z.\, z \supset x, (z - 1 \supset y, \bot)$$

$$(2.22)\quad \langle x_0, x_1, \ldots, x_n\rangle = \lambda z.\, z \supset x_0, \langle x_1, \ldots, x_n\rangle(z - 1).$$

Obviously we should formalize the subscript notation so that $u_x = u(x)$; then we find:

$$(2.23)\quad \langle x_0, x_1, \ldots, x_n\rangle_i = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases}$$

This gives us the method of LAMBDA-defining *finite sequences* (in a quite natural way), and the next step is to consider *infinite sequences*. But these are just the functions $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is arbitrary. What we need then is a condition expressible in the language equivalent to saying $u = \hat{p}$ for some p. This is the same as

$$u = \lambda x. \bigcup\{u_i \mid i \in x\}.$$

but the $\cup$- and set-notation is not part of LAMBDA. We are forced into a recursive definition:

$$(2.24)\quad \$ = \mathbf{Y}(\lambda s \lambda u \lambda z.\, z \supset u_0,\ s(\lambda t.\, u_{t+1})(z - 1)).$$

This equation generalizes (2.22) and we have:

$$(2.25)\quad \$(u) = \lambda x. \bigcup\{u_i \mid i \in x\}.$$

Thus the combinator \$"revalues" an element as a distributive function. This suggests introducing theλ-notation for such functions by the equation:

$$(2.26)\quad \lambda n \in \omega.\, \tau = \$(\lambda z.\, \tau[z/n]).$$

With all these conventions LAMBDA-notation becomes very much like ordinary mathematical notation without too much strain.

Suppose that f is any continuous function and $a \in \mathbf{P}\omega$. We can define $p : \omega \to \mathbf{P}\omega$ in the ordinary way by primitive recursion where:

$$p(0) = a;$$

$$p(n + 1) = f(n)(p(n)).$$

The question is: can we give a LAMBDA-definition for $\hat{p}$ (in terms of f and a as constants, say)? The answer is clear, for we can prove:

$$(2.27)\quad \hat{p} = \mathbf{Y}(\lambda u \lambda n \in \omega.\, n \supset a,\ f(n - 1)(u(n - 1))).$$

This already shows that a large part of the definitions of recursion theory can be given in this special language. Of course, simultaneous (primitive) recursions can be transcribed into LAMBDA with the aid of the ordered tuples of (2.22), (2.23) above. But we can go further and connect with partial (and general) recursive functions. We state first a definition.

2.3.10 The graph model

From this point on we see no need to distinguish continuous functions from elements of $\mathbf{P}\omega$; a continuous function will be *identified* with its graph. Note that u is a graph iff $u = \lambda x.\, u(x)$, which is equivalent to Theorem 1.2 (iii). For this reason (functions are graphs) we propose the name *Graph Model* for this model of the λ-calculus. (There is more to LAMBDA than just λ, however.)

The identification of functions with graphs entails that the function space of all continuous functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$ is to be identified (one-to-one) with the subspace

$$\mathbf{FUN} = \{u \mid u = \lambda x.\, u(x)\} \subseteq \mathbf{P}\omega.$$

The identification is *topological* in that the subspace topology agree with the product topology on the function space. This is the topology of pointwise convergence and is closely connected with the lattice structure on the function space which is also defined pointwise (that is, argumentwise). In the notation of λ-abstraction we can express this as the extension of the axiom of extensionality called (ξ^*) in Table 1 of the Introduction. The laws in Table 1 are not the only ones valid in the model, however. We may also note such argumentwise distribution laws as:

$$(2.9) \quad (f \cup g)(x) = f(x) \cup g(x);$$

$$(2.10)\quad (\lambda x.\,\tau) \cup (\lambda x.\,\sigma) = \lambda x.\,(\tau \cup \sigma);$$

$$(2.11)\quad (f \cap g)(x) = f(x) \cap g(x);$$

$$(2.12)\quad (\lambda x.\,\tau) \cap (\lambda x.\,\sigma) = \lambda x.\,(\tau \cap \sigma).$$

In the above f and g must be graphs. It is also true that if $\mathcal{F} \subseteq \mathbf{P}\omega$, then

$$(2.13)\quad \bigcup\{f \mid f \in \mathcal{F}\}(x) = \bigcup\{f(x) \mid f \in \mathcal{F}\},$$

but the same does not hold for $\cap$.

2.3.11 Elementary definitions

We state now a sequence of minor results which show why some simple functions and constants are LAMBDA-definable.

$$(2.14) \quad \bot = (\lambda x.\, x(x))(\lambda x.\, x(x));$$

$$(2.15) \quad x \cup y = (\lambda z.\, 0) \supset x, y; \quad \text{(Hint: } 0, 1 \in \lambda z.\, 0)$$

$$(2.16) \quad \top = \mathbf{Y}(\lambda x.\, 0 \cup (x+1));$$

$$(2.17)\quad x \cap y = \mathbf{Y}(\lambda f \lambda x \lambda y.\, x \supset (y \supset 0, \bot), f(x-1)(y-1)+1)(x)(y).$$

The elements $\bot$ and $\top$ are graphs, by the way, and we can characterize them as the only fixed points of the combinator $\mathbf{K}$:

$$(2.18)\quad a = \lambda x.\, a \quad \text{iff} \quad a = \bot \quad \text{or} \quad a = \top.$$

2.3.12 Sequences

Next we use the notation $\langle x_0, x_1, \ldots, x_{n-1}\rangle$ for the function $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is defined by:

$$p(i) = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases}$$

$$\langle\rangle = \bot \tag{2.19}$$

$$\langle x\rangle = \lambda z.\, z \supset x, \bot \tag{2.20}$$

$$\langle x, y\rangle = \lambda z.\, z \supset x, (z - 1 \supset y, \bot) \tag{2.21}$$

$$\langle x_0, x_1, \ldots, x_n\rangle = \lambda z.\, z \supset x_0, \langle x_1, \ldots, x_n\rangle(z - 1). \tag{2.22}$$

Obviously we should formalize the subscript notation so that $u_x = u(x)$; then we find:

$$\langle x_0, x_1, \ldots, x_n\rangle_i = \begin{cases} x_i & \text{if } i < n; \\ \bot & \text{if } i \geq n. \end{cases} \tag{2.23}$$

This gives us the method of LAMBDA-defining *finite sequences* (in a quite natural way), and the next step is to consider *infinite sequences*. But these are just the functions $\hat{p}$ where $p : \omega \to \mathbf{P}\omega$ is arbitrary. What we need then is a condition expressible in the language equivalent to saying $u = \hat{p}$ for some p. This is the same as

$$u = \lambda x. \bigcup \{u_i \mid i \in x\}.$$

2.3.13 Distributive functions

The $\cup$- and set-notation is not part of LAMBDA. We are forced into a recursive definition:

$$(2.24) \quad \$ = \mathbf{Y}(\lambda s \lambda u \lambda z.\, z \supset u_0,\, s(\lambda t.\, u_{t+1})(z-1)).$$

This equation generalizes (2.22) and we have:

$$(2.25) \quad \$(u) = \lambda x.\, \bigcup \{u_i \mid i \in x\}.$$

Thus the combinator \$"revalues" an element as a distributive function. This suggests introducing theλ-notation for such functions by the equation:

$$(2.26) \quad \lambda n \in \omega.\, \tau = \$(\lambda z.\, \tau[z/n]).$$

With all these conventions LAMBDA-notation becomes very much like ordinary mathematical notation without too much strain.

2.3.14 Primitive recursion

Suppose that f is any continuous function and $a \in \mathbf{P}\omega$. We can define $p : \omega \to \mathbf{P}\omega$ in the ordinary way by primitive recursion where:

$$p(0) = a;$$

$$p(n+1) = f(n)(p(n)).$$

The question is: can we give a LAMBDA-definition for $\hat{p}$ (in terms of f and a as constants, say)? The answer is clear, for we can prove:

$$(2.27) \quad \hat{p} = \mathbf{Y}(\lambda u \lambda n \in \omega.\, n \supset a,\ f(n-1)(u(n-1))).$$

This already shows that a large part of the definitions of recursion theory can be given in this special language. Of course, simultaneous (primitive) recursions can be transcribed into LAMBDA with the aid of the ordered tuples of (2.22), (2.23) above. But we can go further and connect with partial (and general) recursive functions. We state first a definition.

2.3.15 Definition (computable)

DEFINITION. A continuous function f of k-variables is *computable* iff the relationship

$$m \in f(e_{n_0})(e_{n_1})\cdots(e_{n_{k-1}})$$

is recursively enumerable (r.e.) in the integer variables $m, n_0, n_1, \ldots, n_{k-1}$.

If q is a partial recursive function in the usual sense, then we can regard it as a mapping $q : \omega \to \omega \cup \{\bot\}$, where $q(n) = \bot$ means that q is undefined at n. Saying that q is partial recursive is just to say that $m \in q(n)$ is r.e. as a relation in n and m. It is easy to see that this is in turn equivalent to the recursive enumerability of the relationship $m \in \hat{q}(e_n)$; and so our definition is formally a generalization of the usual one. But it is also intuitively reasonable. To "compute" $y = f(x)$, in the one-variable case, we proceed by enumeration. First we begin the enumeration of all finite subsets $e_n \subseteq x$. For each of these f starts up an enumeration of the set $f(e_n)$; so we sit back and observe which $m \in f(e_n)$ by enumeration. The totality of all such m for all $e_n \subseteq x$ forms in the end the set y.

2.3.17 Definability

As a hint for the proof we may note that the method of (2.27) shows that all primitive recursive functions p have the corresponding $\hat{p}$ LAMBDA-definable. Next we remark that a nonempty r.e. set is the range of a primitive recursive function; but the range of p is $\hat{p}(\top)$, which is clearly LAMBDA-definable. That any LAMBDA-definable set (graph) is r.e. is obvious from the definition of the language itself.

Theorem 2.6 THEOREM 2.6 (The definability theorem). *For a k-ary continuous function f, the following are equivalent:*

(i) f is computable;

(ii) $\lambda x_0 \lambda x_1 \cdots \lambda x_{k-1}.\, f(x_0)(x_1)\cdots(x_{k-1})$ as a set is r.e.;

(iii) $\lambda x_0 \lambda x_1 \cdots \lambda x_{k-1}.\, f(x_0)(x_1)\cdots(x_{k-1})$ is LAMBDA-definable.

As a hint for the proof we may note that the method of (2.27) shows that all primitive recursive functions p have the corresponding $\hat{p}$ LAMBDA-definable. Next we remark that a nonempty r.e. set is the range of a primitive recursive function; but the range of p is $\hat{p}(\top)$, which is clearly LAMBDA-definable. That any LAMBDA-definable set (graph) is r.e. is obvious from the definition of the language itself.

We may draw some interesting conclusions from the definability theorem. In the first place, we see that the countable collection $\mathbf{RE} \subseteq \mathbf{P}\omega$ of r.e. sets is closed under application and LAMBDA-definability. Indeed it forms a model for the λ-calculus (axioms (α), (β), and (ξ^*) at least) and it also contains the arithmetical combinators. (Clearly there will be many intermediate submodels.) In the second place, we can see now how very easy it is to interpret λ-calculus in ordinary arithmetical recursion theory by means of quite elementary operations on r.e. sets. Thus the equivalence of λ-definability with partial recursiveness seems not to be all that good a piece of evidence for Church's Thesis. In his 1936 paper (a footnote on p. 346) Church says about λ-definability:

> The fact, however, that two such widely different and (in the opinion of the author) equally natural definitions of effective calculability turn out to be equivalent adds to the strength of the reasons adduced below for believing that they constitute as general a characterization of this notion as is consistent with the usual intuitive understanding of it.

The point never struck the present author as an especially telling one, and the reduction of λ-calculus to r.e. theory shows that the divergence between the theories is not at all wide. Of course it is a pleasant surprise to see how many complicated things can be defined in pure λ-calculus (without arithmetical combinators), but this fact cuts the wrong way as evidence for the thesis (we want stronger theories, not weaker ones). Post systems (or even first-order theories) are much better to mention in this connection, since they are obviously more inclusive in giving enumerations than Turing machines or Herbrand–Gödel recursion equations. But the equivalence proofs are all so easy! What one would like to see is a "natural" definition where the equivalence with r.e. is not just a mechanical exercise involving a few tricks of coding.

In the course of the development in this section we have stated many equations which are not found in Table 1, and which involve new combinators. In conclusion we would like to mention an equation about $\mathbf{Y}$ which holds in the model, which can be stated in pure λ-calculus, and which cannot be proved by ordinary reduction (though we shall not try to justify this last statement here). In order to shorten the calculations, we note from definition (2.8) that $\mathbf{Y}(u) = \mathbf{Y}(\lambda y.\, u(y))$; so by Theorem 2.5 this also equals $u(\mathbf{Y}(u))$.

$$(2.28) \quad \mathbf{Y}(\lambda f \lambda x.\, g(x)(f(x))) = \lambda x.\, \mathbf{Y}(g(x)).$$

Call the left side f' and the right f''. Now $f'' = \lambda x.\, g(x)(\mathbf{Y}(g(x))) = \lambda x.\, g(x)(f''(x))$, thus $f' \subseteq f''$, because f' is a least fixed point. On the other hand $f' = \lambda x.\, g(x)(f'(x))$, so $f'(x) = g(x)(f'(x))$. Thus $f''(x) \subseteq f'(x)$, because $f''(x)$ is a least fixed point. As this holds for all x, we see that $f'' \subseteq f'$; and so they are equal. There must be many other such equations.

Motivation The three conditions meet as follows. Passing from a computable f to its iterated graph replaces $m \in f(e_{n_0})(e_{n_1}) \cdots (e_{n_{k-1}})$ by membership of the iterated pair $(n_0, (n_1, (\cdots, (n_{k-1}, m) \cdots)))$ in that graph, so the function is computable exactly when the graph is r.e. The hint above shows that an r.e. graph is LAMBDA-definable. In the other direction each of the six combinators of Theorem 2.4 is r.e., and application preserves r.e. sets: $m \in u(x)$ is an existential quantification over a finite $e_n \subseteq x$ together with a bounded universal quantification, and membership in u and in x occurs positively.

2.3.18 A law of Y

In the course of the development in this section we have stated many equations which are not found in Table 1, and which involve new combinators. In conclusion we would like to mention an equation about $\mathbf{Y}$ which holds in the model, which can be stated in pure λ-calculus, and which cannot be proved by ordinary reduction (though we shall not try to justify this last statement here). In order to shorten the calculations, we note from definition (2.8) that $\mathbf{Y}(u) = \mathbf{Y}(\lambda y.\, u(y))$; so by Theorem 2.5 this also equals $u(\mathbf{Y}(u))$.

$$(2.28) \quad \mathbf{Y}(\lambda f \lambda x.\, g(x)(f(x))) = \lambda x.\, \mathbf{Y}(g(x)).$$

Call the left side f' and the right f''. Now $f'' = \lambda x.\, g(x)(\mathbf{Y}(g(x))) = \lambda x.\, g(x)(f''(x))$, thus $f' \subseteq f''$, because f' is a least fixed point. On the other hand $f' = \lambda x.\, g(x)(f'(x))$, so $f'(x) = g(x)(f'(x))$. Thus $f''(x) \subseteq f'(x)$, because $f''(x)$ is a least fixed point. As this holds for all x, we see that $f'' \subseteq f'$; and so they are equal. There must be many other such equations.

2.4 Retracts and data types

Historical note. A retract is an ordinary notion of topology. The use of computable retracts as data types, the operations on those retracts, and the recursive definitions by fixed-point equations are Scott's. A continuous lattice, in the sense of Scott (1972), has continuous meet and join, and as a space it is a T_0-space satisfying the extension theorem. The connection between lattices and fixed points was already known. The set of all retracts is a complete lattice by Theorem 4.1, and it is not itself a continuous lattice. Ershov solved that question after the body of the paper was written; Hosono and Sato (1975) found essentially the same argument independently. The argument is given with the ordering of retracts. The correspondence was Scott's introduction to Ershov's numeration theory. Applications to the semantics of flow diagrams are in Scott (1971), and were taken up by Goguen et al. (1975) and by Reynolds (1974).

Dependencies. Inside Retracts, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

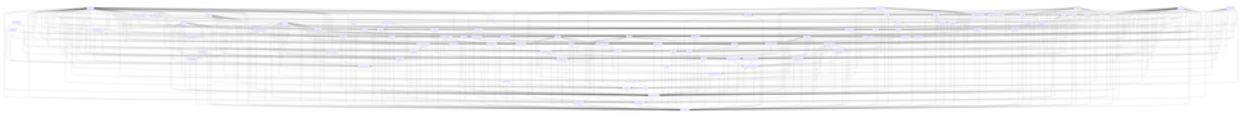

Figure 22: Retracts and data types.

Data can be structured in many ways: ordered tuples, lists, arrays, trees, streams, and even operations and functions. The last point becomes clear if one thinks of *parameters*. We would normally hardly consider the pairing function $\lambda x \lambda y.\, \langle x, y\rangle$ as being in itself a piece of data. But if we treat the first variable as a *parameter*, then it can be specialized to a *fixed value*, say the element a, producing the function $\lambda y.\, \langle a, y\rangle$. This function is more likely to be the output of some process and *in itself* can be considered as a datum. It is rather like one *whole row* of a matrix. If we were to regard a two-argument function f as being a matrix, then its ath row would be exactly $\lambda y.\, f(a)(y)$. If s were a selection function, then, for example, $\lambda y.\, f(s(y))(y)$ would represent the selection of one element out of each column of the matrix. This selection could be taken as a specialization of parameters in the operator $\lambda u \lambda v \lambda y.\, u(v(y))(y)$. We have not been very definite here about the exact nature of the fixed a, f, or s, or the range of the variable y or the range of values of the function f. The point is only to recall a few elements of structure and to suggest an abstract view of data going beyond the usual iterated arrays and trees.

What then is a *data type*? Answer: a type of data. That is to say, a collection of data that have been grouped together for reasons of similarity of structure or perhaps mere convenience. Thus the collection may very well be a mixed bag, but more often than not canons of taste or demands of simplicity dictate an

adherence to regularity. The grouping may be formed to eliminate irrelevant objects and focus the attention in other ways. It is frequently a matter of good organization that aids the understanding of complex definitions. In programming languages, one of the major reasons for making an explicit declaration of a data type (that is, the restriction of certain variables to certain *"modes"*) is that the computed objects of that type can enjoy a special *representation* in the machine that allows the manipulation of these objects via the chosen representation to be reasonably efficient. This is a very critical matter for good language design and good compiler writing. In this report, however, we cannot discuss the problems of representation, important as they may be. Our objective here is conceptual organization, and we wish to show how such ideas, in the language for computable functions used here, can find the proper expression.

Which are the data types that can be defined in LAMBDA? No final answer can be given since the number is infinite and inexhaustible. From one point of view, however, there is only one: $\mathbf{P}\omega$ itself. It is the universal type and all other types are subtypes of it; so $\mathbf{P}\omega$ plays a primary role in this exposition. But in a way it is too big, or at least too complex, since each of its elements can be used in so many different ways. When we specify a subtype the intention is to restrict attention to a special use. But even the various subtypes overlap, and so the same elements still get different uses. Style in writing definitions will usually make the differentiation clear though. The main innovation to be described in this section is the use of LAMBDA expressions to define types *as well as* elements. Certain expressions define *retracts* (or better: retraction mappings), and it is the *ranges* (or as we shall see: *sets of finite points*) of such retracts that form the groupings into types. Thus LAMBDA provides a calculus of type definitions including *recursive* type definitions. Examples will be explained both here and in the following sections. Note that types as retracts turn out to be types as *lattices*, that is, types of partial and many-valued objects. The problem of cutting these lattice types down to the perfect or complete objects is discussed in § 6. Another view of types and functionality of mappings is presented in § 7.

The notion of a retract comes from (analytic) topology, but it seems almost an accident that the idea can be applied in the present context. The word is employed not because there is some deep tie-up with topology but because it is short and rather descriptive. Three easy examples will motivate the general plan:

$$(4.1) \quad \mathbf{fun} = \lambda u \lambda x.\, u(x);$$

$$(4.2) \quad \mathbf{pair} = \lambda u.\, \langle u_0, u_1 \rangle;$$

$$(4.3) \quad \mathbf{bool} = \lambda u.\, u \sqsupset 0, 1.$$

Here $\sqsupset$ is the *doubly strict conditional* defined by

$$(4.4) \quad z \sqsupset x, y = z \supset (z \supset x, \top), (z \supset \top, y),$$

which has the property that if z is both zero and positive, then it takes the value $\top$ instead of the value $x \cup y$.

2.5 Closure operations and algebraic lattices

Historical note. Algebraic lattices and closure operations predate the paper: Grätzer (1968) for the lattices, Tarski (1930) for the closures. Per Martin-Löf and Peter Hancock suggested that the continuous closures form a universe, and the construction of $\mathbf{V}$ is essentially theirs. The limit theorem is Scott's.

Dependencies. Inside Closures, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 23: Closure operations and algebraic lattices.

Given any family of (finitary) operations on a set (say, ω) there is a closure operation defined on the subsets of that set obtained by forming the *least subset* including the given elements and *closed* under the operations. Examples are very familiar from algebra: the subgroup generated by a set of elements, the subspace spanned by a set of vectors, the convex hull of a set of geometric points. We simplify matters here by restricting attention to closures operating on sets in $\mathbf{P}\omega$, but the idea is quite general. The main point about these "algebraic" closure operations—as distinguished from topological closure operations—is that they are *continuous*. Thus, in the case of subgroups, if an element belongs to the subgroup generated by some elements, then it also belongs to the subgroup generated by *finitely* many of them. In the context of $\mathbf{P}\omega$ we can state the characteristic condition very simply.

2.6 Subsets and their classification

Historical note. The classification of these subsets by notions from descriptive set theory, and the connection with Wadge reducibility, are in the work of Adrian Tang. The normal forms for the classes, such as Table 3, are Scott's.

Dependencies. Inside Classification, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 24: Subsets and their classification.

Retracts produce very special subsets of $\mathbf{P}\omega$: a retract always has a nonempty range which forms a lattice under $\sqsubseteq$. For example, the range of **int** is $\{\bot, \top\} \cup \omega$. We often wish to eliminate $\bot$ and $\top$; and with a retract like **tree** the situation is more complex, since combinations like $\langle 1, \langle\langle 1, \langle \bot, \langle 0\rangle\rangle\rangle, \top\rangle\rangle$ might require elimination. In these two cases the method is simple.

Consider these two functions:

$$\mathbf{mid} = \lambda x : \mathbf{int}.\, x \supset 0, 0 \tag{6.1}$$

$$\mathbf{perf} = \lambda u : \mathbf{tree}.\, \mathbf{which}(u) \supset 0,\ \Delta(\mathbf{perf}(\mathbf{fst}(\mathbf{out}(u))))(\mathbf{perf}(\mathbf{snd}(\mathbf{out}(u)))) \tag{6.2}$$

where Δ is a special combinator:

$$\Delta = \lambda x \lambda y.\, (x \supset (y \supset 0, \top), \top) \cup (y \supset (x \supset 0, \top), \top). \tag{6.3}$$

We find that $\omega = \{x : \mathbf{int} \mid \mathbf{mid}(x) = 0\}$. In the case of trees, note first this behavior of Δ:

Δ	$\bot$	0	$\top$
$\bot$	$\bot$	$\bot$	$\top$
0	$\bot$	0	$\top$
$\top$	$\top$	$\top$	$\top$

The question is: what subset is $\{u : \mathbf{tree} \mid \mathbf{perf}(u) = 0\}$?

Now **perf** is defined recursively. We can see that

$$\mathbf{perf}(\bot) = \bot, \quad \mathbf{perf}(\top) = \top, \quad \mathbf{perf}(\langle 0\rangle) = 0,$$

and

$$\mathbf{perf}(\langle 1, \langle x, y\rangle\rangle) = \Delta(\mathbf{perf}(x))(\mathbf{perf}(y))$$

when $x, y : \mathbf{tree}$. Every tree, aside from $\top$ or $\bot$, is either *atomic* or a pair of trees. The atomic tree is "perfect" (that is, $\mathbf{perf}(\langle 0\rangle) = 0$). A finite tree which does not contain $\bot$ or $\top$ is perfect—as we can see inductively using the table above for Δ. An infinite tree is never perfect: either some branch ends in $\top$ and **perf** maps it to $\top$, or $\top$ is never reached and **perf** maps it to $\bot$. Thus the subset in question is then seen to be the set of *finite* trees generated from the atom by pairing. This is clearly a desirable subset, and it is sorted out by a function with a simple recursive definition. The general question is: what subsets can be characterized by equations? The answer can be given by reference to the topology of $\mathbf{P}\omega$.

2.7 Total functions and functionality

Historical note. Functionality had long been studied in combinatory logic. Hindley, Lercher, and Seldin (1972) is the introduction Scott used. This section is his reading of that theory in $\mathbf{P}\omega$. The connection with the functional interpretation of intuitionistic logic goes back to Curry and Kleene, and Theorem 7.3 is the standard result of that interpretation. Theorem 7.4, that the obvious typing characterizes the iterators, is due to Gordon Plotkin.

Dependencies. Inside Functionality, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 25: Total functions and functionality.

There is an inevitable conflict between the concepts of *total* and *partial* functions: we desire the former, but it is the latter we usually get. Total functions are better because they are "well-defined" at all their arguments, but the rub is that there is no general way of deciding when a *definition* is going to be well-defined in all its uses. In analysis we have singularities, and in recursion theory we have endless, nonfinishing computations. In the present theory we have in effect evaded the question in two ways. First we have embraced the partial function as the norm. But secondly, and possibly confusingly, the multiple-valued functions are normal, total functions from $\mathbf{P}\omega$ into $\mathbf{P}\omega$. The point, of course, is that we are making a *model* of the partial functions in terms of ordinary mathematical functions. But note that the success of the *model* lies in *not* using arbitrary functions: it is only the continuous functions that correspond to the kind of partial functions we wanted to study. It would be a mistake to think of the variables in λ-calculus as ranging over arbitrary functions—and this mistake was made by both Church and Curry. The fixed-point operator $\mathbf{Y}$ shows that we must restrict attention to functions which do have fixed points. It is certainly the case that $\mathbf{P}\omega$ is not the only model for the λ-calculus, but it is a very satisfactory model and is rich enough to illustrate what can and what cannot be done with partial functions.

Whatever the pleasures of partial functions (and the multiple-valued ones, too), the desire for total functions remains. Take the integers. We are more interested in ω than $\omega \cup \{\bot, \top\}$. Since the multiple values $\bot$ and $\top$ are but two in number, it is easy to avoid them. The problem becomes tiresome in considering functions, however. The lattice represented by the retract $\mathbf{int}\circ \to \mathbf{int}$ is much too large, in that there are as many nontotal functions in this domain as total ones. The aim of the present section is to introduce an interpretation of a theory of functionality in the model $\mathbf{P}\omega$ that provides a convenient way of restricting attention to the functions (or other objects) that are total in the desired sense. The theory of functionality is rather like proposals of Curry, but not quite the same for important reasons as we will see.

In the theory of retracts of §§ 5 and 6, the plan of "restricting attention" was the very simple one of restricting to a *subset*. It was made notationally simple as the subsets in question could be parameterized by continuous functions. The retraction mappings stand in for their ranges. Even better, certain continuous functions act on these retractions as space-forming functors (such as $\oplus$ and $\circ \to$), which gives greater notational simplicity because one language is able to serve for several tasks. When we pass to the theory of total functions, this same kind of simplicity is no longer possible owing to an increase in quantifier complexity in the necessary definitions. (This remark is made definite below.) Another point where there is some loss of simplicity concerns the representation of entities in $\mathbf{P}\omega$: subsets will no longer be enough, since we will need *quotients* of subsets. This is not a very startling point. Many constructions are affected in a natural way via equivalence classes. An equivalence relation makes you blind to certain distinctions. It may be easier also to remain a bit blind than to search for the most beautiful representative of an equivalence class: there may be nothing to choose between several candidates, and it can cost too much effort to attempt a choice. Thus our first agreement is that for many purposes a *kind* of object can be taken as a set of equivalence classes for an equivalence relation on a subset of $\mathbf{P}\omega$.

Because $\mathbf{P}\omega$ is closed under the pairing function $\lambda x \lambda y.\, \langle x, y\rangle$, we shall construe relations on subsets of $\mathbf{P}\omega$ as subsets of $\mathbf{P}\omega$ all of whose elements are ordered pairs. That is, a relation A satisfies this inclusion:

$$(7.1) \quad A \subseteq \{\langle x, y\rangle \mid x, y \in \mathbf{P}\omega\}.$$

- Definition (equivalence)

- Theorem 7.1
- Theorem 7.2
- Theorem 7.3
- Theorem 7.4

2.8 Enumeration and degrees

Historical note. Reduction to a few combinators is old in combinatory logic. The device special to this model is (3.1), which folds the arithmetical combinators into the one combinator $\mathbf{G}$. The Gödel numbering and the second recursion theorem are the standard constructions, written so that arithmetic and the type-free combinators share a notation, and the incompleteness theorem is the standard one in that notation. Theorem 3.5 is the argument of Myhill and Shepherdson (1955); Martin Hyland pointed out the connection. Theorem 3.6 restates enumeration degrees, as in Rogers (1967), Sasso (1975), and Gutteridge (1971). Scott notes that this area was underdeveloped beside the theory of Turing degrees. Semigroups of combinators had been discussed by Church and by Böhm, and Theorem 3.7 reads that discussion inside $\mathbf{RE} \cap \mathbf{FUN}$.

Dependencies. Inside Enumeration, each box is one Lean file. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 26: Enumeration and degrees.

A great advantage of the combinators from the formal point of view is that (bound) variables are eliminated in favor of "algebraic" combinations. The disadvantage is that the algebra is not all that pretty, as the combinations tend to get rather long and general laws are rather few. Nevertheless as a technical device it is mildly remarkable that we can have a notation for all r.e. sets requiring so few primitives. In the model defined here the reduction to one combinator rests on a lemma about conditionals:

$$(3.1) \quad \mathbf{cond}(x)(y)(\mathbf{cond}(x)(y)) = y.$$

Recall that $\mathbf{cond}$ (or $\supset$) is a test for zero, so that:

$$(3.2) \quad \mathbf{cond}(x)(y)(0) = x.$$

This suggests that we lump all combinators of Theorem 2.4 into this one:

$$(3.3) \quad \mathbf{G} = \mathbf{cond}(\langle \mathbf{suc}, \mathbf{pred}, \mathbf{cond}, \mathbf{K}, \mathbf{S} \rangle)(0).$$

We can then readily prove:

- Theorem 3.1
- Theorem 3.2
- Theorem 3.3
- Theorem 3.4
- Theorem 3.5
- Theorem 3.6

- Theorem 3.7

3 Neighborhood Systems (1980)

Dependency diagram. Each box is one section. The arrowhead is on the section that imports, and the number on it is how many import lines run that way. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it has no arrow.

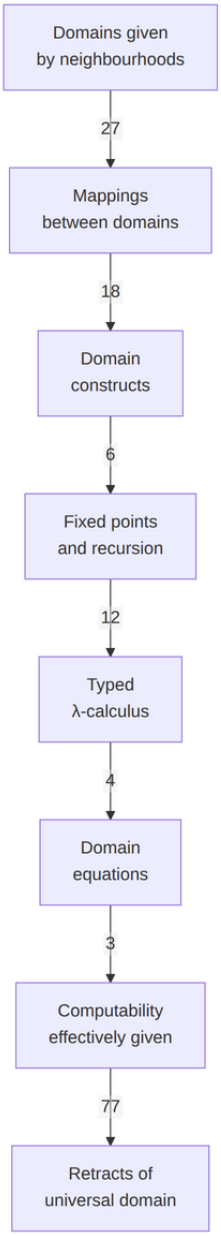

Figure 27: Neighborhood Systems (1980).

3.1 Introduction

These notes were written in conjunction with the lectures delivered by me for the Semantics of Programming Languages sequence during Michaelmas Term 1980 at Oxford. I started writing around the first week of October and finished at the end of November. The purpose of the course was to provide the foundations needed for the method of denotational semantics; in particular, I wanted to make the connections with recursive function theory more definite and to show explicit, effectively given solutions to domain equations. Roughly, these chapters cover the first half of the book of J.E. Stoy. I plan soon to expand the notes into a book by adding additional chapters on other theoretical topics that time did not permit me to cover in one eight-week term.

When I started writing Lecture I in October, I did not know what the later lectures would contain: I could see no further ahead than part of Lecture III in the beginning. The lectures had to be typed in advance of the class meetings, however, so there was at the time of composition no opportunity for second thoughts of any major proportions: I had to write the text straight through. As a consequence there are many remarks I would like to transpose and many additional points of explanation I see are needed; further worked examples and easier exercises are also required. During the spring, after receiving many helpful comments, I was able to introduce a few changes in the text and make some necessary corrections. However, a complete retyping was impossible. Nevertheless, this preliminary version of the book seems to provide a quite detailed introduction and is sufficient to exhibit the scope of the approach and several applications.

The idea of using neighbourhood systems to give set-theoretical representations of domains had been in the back of

my mind for some time in connection with specific examples. But the thought that a systematic development along these lines might be easier to follow than the more abstract lattice-theoretic and topological approach used by myself and others in many publications only came to me during the IFIP Working Group 2.2 meeting in Copenhagen in mid-June 1980. I gave a brief public presentation at ICALP '80 in Holland in mid-July.

One large mistake I have made is to de-emphasize partial orderings too much, since at the right point the concepts and the language are in fact helpful. The basic plan is that, instead of axiomatizing the theory using partial orderings, the necessary facts come out as *theorems*. For a neighbourhood system $\mathcal{D}$, the set of elements $|\mathcal{D}|$, which consists of filters, is naturally partially ordered. And approximable mappings naturally *preserve* the ordering. And so on. The advantage I see from the point of view of exposition is that properties can be brought out one at a time instead of having to put them down all in advance of any experience with the ideas. My own feeling after writing these chapters is that the plan has worked out far better than I could have dared to hope. I was especially glad that I could generate so many *exercises*, and I hope eventually to provide many more. One interesting place at which partial orderings prove their usefulness is in visualizing domains. As it stands now the text does not contain enough in the way of pictures. This will have to be remedied in a future version. Undoubtedly to include enough explanation, several of the lectures will have to be sub-divided into separate chapters.

One major improvement is needed: to bring Exercise 2.22 into the main text. I did not know in advance how often I would need this result for giving (easy) set-theoretical characterizations of domains and structure on them. This will be an easy repair, but it will cause quite a bit of rewriting. Clearly

much more has to be said about the interplay between elements and neighbourhoods. In particular, the character of the elements of a domain, like the power set of a set, has not been sufficiently illustrated, and quite a bit of expansion on this topic is also needed.

Finally I have to explain that I had no time whatsoever to put in references and a bibliography. The ideas I have used have occurred to many, many people who have worked on domains, and I do not wish to claim

originality. I *am* claiming some advantage to my style of representation, but I fully realize that a published version will have to have detailed historical references and notes at the ends of the lectures. Needless to say I should very much appreciate any advice or criticism from readers of this preliminary version.

I would like to give a warm word of thanks to the many people who have already commented on the preliminary text both at Oxford and in Boston, where I gave lectures. Very special thanks are due to Steve Comer and Steve Brookes, who spent many hours proof reading the typescripts. The biggest word of thanks, however, is reserved for Elsie Hinkes who, under very considerable pressure, did a wonderful job of typing.

3.2 Domains given by neighbourhoods

Dependency diagram. Each box is one item. The arrowhead is on the item that imports. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it is not shown. Blue is a definition, green a factoid, amber an example, red a theorem, and indigo an exercise.

Figure 28: Domains given by neighbourhoods.

3.2.1 Introduction

LECTURE I DOMAINS GIVEN BY NEIGHBOURHOODS

Often an object (or element) can be determined by a selection of its properties. Often it is also the case that it is easier (more convenient, more elementary) to think of these properties than it is to think of the elements themselves. Let us term the properties under consideration *neighbourhoods*, the family of those allowed a *neighbourhood system*.

Generally, the collection of these neighbourhoods is, for one reason or another, somewhat restricted; that is, a completely arbitrary property may not be allowable as a neighbourhood. Therefore, the elements determined by selections of neighbourhoods may not be as separable into the discrete objects common to the classical view of set theory. This is particularly true in working with infinite objects: it is hard to specify an infinite element completely. The theory of elements to be studied here, then, is going to permit *partial elements* as well as *total elements*, and each neighbourhood system will define a *domain* of such elements.

Since we may wish to use a neighbourhood system to introduce elements not previously investigated, the

neighbourhoods do not have to be regarded as sets of the as-yet-to-be-defined objects. We can take a non-empty set Δ of *tokens* (or "traces") that function as "parts" of elements — or even as parts of "descriptions" of elements. Then a neighbourhood is a subset $X \subseteq \Delta$ containing all those tokens that provide sufficient information when taken together to "approximate" a possible element up to a certain "degree". All these words in inverted commas are vague, and in any case we shall have at the start only a *qualitative* theory of "degree of approximation". A token should be considered as a very "rough" representative of an element, and a neighbourhood should be regarded as "smoothing out" irrelevant details by grouping together *all* those representatives sharing some common feature. One neighbourhood, then,

may be only a very incomplete specification of an (ideal) element; fuller specifications can be secured by taking "convergent" sequences of neighbourhoods. Even then convergence need not be to a total element.

Let us call the family of allowed neighbourhoods $\mathcal{D}$; it is a family of subsets of the set Δ. An obvious first question is: when are two neighbourhoods $X, Y \in \mathcal{D}$ neighbourhoods of the "same" element? This question of course generalizes to a (finite) sequence of neighbourhoods. This property we will call the *consistency* of the sequence of neighbourhoods. By definition this will mean that the given neighbourhoods all contain a common neighbourhood in $\mathcal{D}$. That is, for X, Y to be consistent, there must be a $Z \in \mathcal{D}$ with $Z \subseteq X$ and $Z \subseteq Y$. This is not a very informative definition, but it has something of the flavour of a notion of consistency insofar as it can be expressed within $\mathcal{D}$. When consistency holds it seems reasonable enough at first glance to say that the intersection $X \cap Y$ is also an approximation to this common element. If this is reasonable, then $X \cap Y$ should also be regarded as a neighbourhood. This assumption has many consequences, but as a preliminary theory of approximation we will find it quite workable with many natural instances. Taking intersections just means taking more and more properties of the element and putting them together "conjunctively". It is something we do all the time. We therefore accept the idea for the present for giving our first principal definition.

3.2.2 Definition 1.1 — neighbourhood system

DEFINITION 1.1. A family $\mathcal{D}$ of subsets of a given set Δ is called a *neighbourhood system* (over Δ) iff it is a non-empty family closed under the intersection of finite consistent sequences of neighbourhoods. That is to say, $\mathcal{D}$ must fulfill these two conditions:

(i) $\Delta \in \mathcal{D}$;

(ii) whenever $X, Y, Z \in \mathcal{D}$ and $Z \subseteq X \cap Y$, then $X \cap Y \in \mathcal{D}$. □

We remark that by convention Δ corresponds to the intersection of an empty sequence of neighbourhoods; in particular, see Factoid 1.1.

3.2.3 Factoid 1.1 — empty intersection is delta; recursive finite intersection

Factoid 1.1a — empty intersection is delta

$$\bigcap_{i<n} X_i = \Delta, \text{ if } n = 0;$$

Factoid 1.1b — recursive finite intersection

$$= \left(\bigcap_{i<n-1} X_i \right) \cap X_{n-1}, \text{ if } n > 0.$$

Of course, from (ii), we can extend the intersection property to any finite sequence. Consequently, we can say $X_0, \ldots, X_{n-1}$ is consistent in $\mathcal{D}$ iff

$$\bigcap_{i<n} X_i \in \mathcal{D}.$$

Some examples will help us understand the notions better.

3.2.6 Example 1.4 — finite binary tree

EXAMPLE 1.4. Let $\Delta = \{\Lambda, 0, 1, 00, 01, 10, 11\}$ and let $\mathcal{D} = \{\Delta, \{0, 00, 01\}, \{1, 10, 11\}, \{00\}, \{01\}, \{10\}, \{11\}\}$.

Or more understandably in pictures:

The tokens are finite sequences of 0's and 1's (up to length 2) with Λ the empty sequence; they form — in the picture — the binary tree with the sequences as the nodes. The neighbourhoods are the subtrees of all nodes above a given node. Obviously this can be generalized to sequences of any length (and to trees less regular than the binary tree). The total elements of the example correspond to the top nodes 00, 01, 10, 11 and the lower nodes to the partial elements. When we are not at a top node we have only partially determined a sequence, and the branching indicates that we have some choice as to how the sequence can be extended. □

It should be noted that, in these three examples, the reason that we have a neighbourhood system is a simple consequence of a

Resolutions from the image: "is unique" (not "in unique"); $\mathcal{D}$ begins with Δ, not Λ; Pass 1's nested-box diagram matches the neighborhood boundaries in the scan; em dashes around "in the picture" as in the source.

3.2.9 Factoid 1.5 — consistent iff nonempty; equivalent sequences same limit

Factoid 1.5a — consistent iff nonempty This system is a direct generalization of Example 1.2., which was special owing to the small number of tokens. (The other examples were special by virtue of the choice of neighbourhoods.) The verification that the present $\mathcal{D}$ is a neighbourhood system rests on nothing more than the remark that sets are consistent in $\mathcal{D}$ iff they have a non-empty intersection. Clearly the arrangement of neighbourhoods in $\mathcal{D}$ can be as varied as a four-element set will allow; if Δ were made larger, the possible combinations of neighbourhoods could be made as complex as you wish. □

Having some idea now of the variety of neighbourhood systems, we have to discuss what it is they do. As stressed before, the tokens do not have to correspond directly to the elements; but where, we ask, do the elements come from? One obvious suggestion for determining an element is to produce a sequence of "better and better" neighbourhoods:

$$X_0 \supseteq X_1 \supseteq \cdots \supseteq X_n \supseteq \cdots$$

Trivially, any finite initial segment of this sequence is consistent, and so each X_n is a partial approximation to the "limit". If $\mathcal{D}$ were always to be taken as *finite*, of course, there would be no point in discussing limits since any such sequence would eventually be constant. The elements in the finite case would therefore be completely represented by neighbourhoods with the *minimal* neighbourhoods corresponding to the total elements. But there are many reasons to go beyond the finite (though perhaps not too far beyond).

Suppose $\langle Y_n \rangle_{n=0}^{\infty}$ is another "convergent" sequence with

$Y_{n+1} \subseteq Y_n$ for all indices: when do the two sequences of neighbourhoods determine the *same limit*? The two sequences can surely be different; for example, $\langle Y_n \rangle_{n=0}^{\infty}$ could be a subsequence of $\langle X_n \rangle_{n=0}^{\infty}$, say, $Y_n = X_{2n}$. Still we would want to say that the same limit is obtained. Without being given any further structure on the neighbourhoods, a simple answer is just to say that each sequence goes *equally deep* as the other:

for each m there is an n with $X_n \subseteq Y_m$, and

for each n there is an m with $Y_m \subseteq X_n$.

This definition obviously puts sequences into equivalence classes, and so elements could be identified with these. But such a definition is clumsy for two reasons: it is always tiresome to work with equivalence classes, and there is no reason to think that simple infinite sequences are adequate for determining elements without some rather drastic assumptions on $\mathcal{D}$. Nevertheless, the idea is *suggestive*; we just have to find some construct to represent elements in a unique way and to phrase it in a general enough manner.

Start with $\langle X_n \rangle_{n=0}^{\infty}$ again, which "converges" as before. Think of all the other sequences equivalent to this one in the sense just defined. We can define the class of all terms of all such sequences very easily as being the family:

$$x = \{Z \in \mathcal{D} \mid X_n \subseteq Z \text{ for some } n\}.$$

Factoid 1.5b — equivalent sequences same limit It is easy to prove that if we form the analogous class for $\langle Y_n \rangle_{n=0}^{\infty}$, then the two families are *equal* if and only if the sequences are *equivalent*. Thus, we seem justified in letting x represent the limit of $\langle X_n \rangle_{n=0}^{\infty}$. All we have to do now is to remark on what sort of class x is as a subfamily of $\mathcal{D}$; what we abstract from the construction, however, will be just a bit more general than taking those x that result from sequences.

3.2.10 Definition 1.6 — ideal elements

DEFINITION 1.6. The (ideal) elements of a neighbourhood system $\mathcal{D}$ are those subfamilies $x \subseteq \mathcal{D}$ where:

(i) $\Delta \in x$;

(ii) $X, Y \in x$ always implies $X \cap Y \in x$; and

(iii) whenever $X \in x$ and $X \subseteq Y \in \mathcal{D}$, then $Y \in x$.

The *domain* of all such elements is written as $|\mathcal{D}|$. □

The idea of 1.6 is a well-known mathematical device: the families x satisfying (i)–(iii) are usually called *filters*. Most frequently the emphasis is put on the *maximal* filters, and these would be our *total* elements; however, in general, the proof that maximal filters exist is non-constructive, so for our purposes it is better not to neglect the partial filters. When maximal filters can be found, well and good, but we do not have to insist on them. Note that the generality of 1.6 is achieved by not requiring that there is a sequence of neighbourhoods that "generates" the filter x. (See Exercise 1.22.)

We have often said that neighbourhoods determine partial elements by themselves; we now make this remark precise.

Factoid 1.7a1 — principals are one-one It is obvious that the correspondence between X and $\uparrow X$ is one-one and inclusion *reversing*, in the sense that

Factoid 1.7a2 — inclusion-reversing principals

$$X \subseteq Y \quad \text{iff} \quad \uparrow Y \subseteq \uparrow X$$

for all $X, Y \in \mathcal{D}$. But, except in very special cases, there is much more to $|\mathcal{D}|$ than just the finite elements. Much of our investigation will be concerned with finding out how much more. The finite elements are, in a certain sense, "dense" in $|\mathcal{D}|$, however, because it is also obvious from the definitions that for each $x \in |\mathcal{D}|$

Factoid 1.7b — union of principal filters

$$x = \bigcup \{\uparrow X \mid X \in x\}.$$

That is, every element is a certain type of "limit" of finite elements. (This statement is made more precise in Exercise 1.21)

We note that we have now had several occasions to use inclusion relationships between elements; this is an important relationship, and we give it a special name.

3.2.14 Factoid 1.8 — bottom element; bottom is least; finite filters are principal; prefix order; union of finite approximations

Factoid 1.8a1 — bottom element DEFINITION 1.8. For $x, y \in |\mathcal{D}|$, we say that x *approximates* y iff $x \subseteq y$. The element that approximates all others, $\{\Delta\}$, is called $\perp$ (read: *bottom*); it is the "least defined" element, or the "most partial" element. Elements maximal with respect to the approximation relation are called *total elements*. □

Factoid 1.8a2 — bottom is least DEFINITION 1.8. For $x, y \in |\mathcal{D}|$, we say that x *approximates* y iff $x \subseteq y$. The element that approximates all others, $\{\Delta\}$, is called $\perp$ (read: *bottom*); it is the "least defined" element, or the "most partial" element. Elements maximal with respect to the approximation relation are called *total elements*. □

Factoid 1.8b — finite filters are principal EXAMPLES 1.2 – 1.5 (Revisited). The examples as given were all finite, so any explicitly given filter x is principal, the element is finite, the minimal $X \in x$ tells us all we need to know. In such simple situations there is essentially no difference between elements and neighbourhoods — except for the reversal of the order as noted. This (necessary) reversal should not, however, become a matter of confusion: the smaller the neighbourhood has become, the more it has "converged", and so the better defined the element has become. In the approximation relation the "poorer" elements are placed below the "better" with the total up at the top. This will become clearer in discussing "infinite" elements.

Example 1.3 will be generalized in Exercise 1.12. Let us here generalize first 1.4. We let

$$\Delta = \Sigma^*,$$

where $\Sigma = \{0, 1\}$ and Σ^* means the set of all finite sequences of 0's and 1's, with Λ being the empty sequence. We write $\sigma\tau$ for the *concatenation* or *juxtaposition* of two sequences $\sigma, \tau \in \Sigma^*$. Define

$$B = \{\sigma\Sigma^* \mid \sigma \in \Sigma^*\}, \text{ where}$$

$$\sigma X = \{\sigma\tau \mid \tau \in X\},$$

for an arbitrary set $X \subseteq \Sigma^*$. In other words, a neighbourhood in B consists of all *extensions* of a given sequence σ. (Refer back to the finite version of 1.4.) We use the letter "B" to remind us of "binary", and this is an example we shall refer to many times. The proof (if it is not obvious) that B is a neighbourhood system should be done as an exercise.

What do we find in $|B|$? Of course $\perp = \{\Delta\} \in |B|$. For any $x \in |B|$ and $\sigma \in \Sigma^*$ define

$$\sigma x = \{Y \mid \sigma X \subseteq Y \text{ some } X \in x\}.$$

Factoid 1.8c — prefix order Again there is an exercise here to show $\sigma x \in |B|$. In particular $\sigma \perp \in |B|$ for all $\sigma \in \Sigma^*$, and these are just the finite elements. The minimal element of $\sigma \perp$ is $\sigma\Delta$. Note that $\sigma_0 \perp \subseteq \sigma_1 \perp$ if and only if σ_0 is an *initial segment* of the sequence σ_1.

If now $x \in |B|$ is any explicitly given element (that is, if we know for any $X \in B$ whether or not $X \in x$), we have but to work out from these definitions that

Factoid 1.8d — union of finite approximations

$$x = \bigcup_{n=0}^{\infty} \sigma_n \perp,$$

where the $\sigma_n \in \Sigma^*$ and each σ_n is an initial segment of the next σ_{n+1}. *In general, in any domain, an element is uniquely determined by its finite approximations, and we are just making this explicit in* $|B|$. When we have complete knowledge of x, then there are two cases: either the approximations $\sigma_n \perp$ become constant from some point on (where $n > n_0$), or not. In the first case x is finite and equal to $\sigma_{n_0} \perp$; in the second case x is infinite and the σ_n fill out an infinite (one-way) sequence.

The generalization of 1.5 to the infinite case where $\Delta = \mathbf{N} = \{0, 1, 2, 3, \ldots, n, \ldots\}$ can be made in more than one way: for instance either we use as neighbourhoods *all* non-empty subsets of Δ or just those omitting but a finite number of integers. And, as will become apparent, there are other choices giving domains of quite different characters. □

Many constructions (choices of $\mathcal{D}$) lead to the "same" domain; "sameness" is an important notion and it is to be defined in terms of "isomorphism", which in turn is to be defined in terms of approximation preserving correspondences.

3.2.16 Definition 1.9 — isomorphic domains

DEFINITION 1.9. Two neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$ determine *isomorphic domains* iff there is a one-one correspondence between $|\mathcal{D}_0|$ and $|\mathcal{D}_1|$ which preserves inclusion between the elements of the domains. In symbols we write $\mathcal{D}_0 \cong \mathcal{D}_1$. □

It is certain that the property of 1.9 is necessary, but it may not be so clear that it is sufficient. We shall in fact prove in the next lecture that an isomorphism between domains always maps finite elements to finite elements, so it always results from a one-one inclusion-preserving correspondence between neighbourhoods. This is surely as strong as could be hoped. This general result is not needed to see that particular domains are isomorphic.

In some of the examples tokens corresponded to total elements and in some to partial elements; it is not difficult to see (ex post facto) that every domain can be presented with tokens exactly corresponding to partial elements.

7

3.2.17 Theorem 1.10 — basic open neighbourhoods

THEOREM 1.10. Given any neighbourhood system $\mathcal{D}$, define for $X \in \mathcal{D}$

$$[X] = \{x \in |\mathcal{D}| \mid X \in x\}.$$

The subsets $[X] \subseteq |\mathcal{D}|$ for $X \in \mathcal{D}$ form a neighbourhood system over $|\mathcal{D}|$ which determines a domain isomorphic to $|\mathcal{D}|$.

Proof: We note first that

(1) $[\Delta] = |\mathcal{D}|$.

Next note that

(2) X, Y are consistent in $\mathcal{D}$ iff $[X] \cap [Y] \neq \emptyset$;

and that for $X, Y \in \mathcal{D}$

(3) $[X] \cap [Y] = [X \cap Y]$ if $X \cap Y \in \mathcal{D}$.

Inasmuch as

(4) $\uparrow X \in [X]$ for all $X \in \mathcal{D}$,

it easily follows that $\mathcal{D}$ and the family

$$\{[X] \mid X \in \mathcal{D}\}$$

are in a one-one, inclusion-preserving correspondence. Thus, we can induce the desired one-one correspondence between the elements of the two systems. □

The import of 1.10 is that the original tokens in Δ can be replaced by the elements of $|\mathcal{D}|$. This process replaces the neighbourhood $X \subseteq \Delta$ by the subset $[X] \subseteq |\mathcal{D}|$. As the passage is inclusion preserving, the domain has not really changed, only its presentation. Though of some theoretical charm, the theorem is not of much use since we still have to get $\mathcal{D}$ from somewhere. It does emphasize, though, that the rôle of the tokens is simply to keep the inclusions (and intersections) of neighbourhoods sorted out. It is *not* always true that the tokens can be identified with the total elements.

The last theorem in this lecture is a result on *closure properties* of a domain with respect to set-theoretical operations which have interesting meanings with respect to approximation.

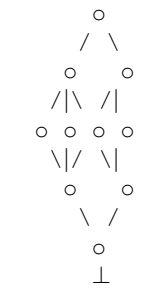
3.2.18 Theorem 1.11 — intersections and directed unions

THEOREM 1.11. If $\mathcal{D}$ is a neighbourhood system and $x_n \in |\mathcal{D}|$ for $n = 0, 1, 2, \ldots$, then

(i) $\bigcap_{n=0}^{\infty} x_n \in |\mathcal{D}|$; and

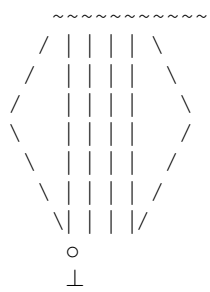
(ii) $\bigcup_{n=0}^{\infty} x_n \in |\mathcal{D}|$, provided

$$x_0 \subseteq x_1 \subseteq x_2 \subseteq \cdots \subseteq x_n \subseteq x_{n+1} \subseteq \cdots .$$



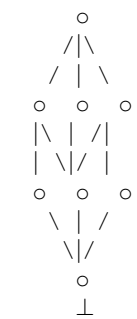
Proof: The conditions of 1.6 have to be checked. For the case of intersection, all of 1.6(i)–(iii) are quite obvious. For the case of union, only 1.6(ii) gives pause and it requires the proviso. If X and Y belong to the union, then $X \in x_n$, say, and $Y \in x_m$. But, either $n < m$ or $m < n$, and if $k = \max(n, m)$, then $X, Y \in x_k$. Since $x_k \in |\mathcal{D}|$, we have $X \cap Y \in x_k$; thus, $X \cap Y$ belongs to the union. This proves (ii). □

In words, the intersection is the best element that is at the same time an approximation to all of the elements x_n; the intersection is exactly what is common to all the given elements. The union on the other hand is just what the (increas-



The union on the other hand is just what the (increasing sequence of the) x_n approximates; the union combines contributions from all the x_n into a "better" element – but no more than that.

In thinking about domains a rough diagram of the partial-ordering relation $\subseteq$ between elements is often helpful. The picture of 1.4 is an example where the nodes represent the elements. Any finite tree growing up from a root node would also be an example. Indeed, any finite partially ordered set with least element would be an example. (Here no distinction between tokens and elements is necessary.) A lattice diagram is also illustrated.



A TREE

A ROUGH PICTURE

A LATTICE

The root node is the element $\bot$ of $|\mathcal{D}|$; there need be no top node $\top$. *Approximation* is represented by a passage from a lower node to a higher node along the rising lines. The system $\mathcal{D}$ of neighbourhoods is the collection of sets each of which is all

the nodes above a given node. For infinite examples, however, care must be given to introduce limit nodes. The first few exercises should be provided with pictures to illustrate the structure.

3.2.25 Exercise 1.18 — consistency of neighbourhood families

Let $\mathcal{D}$ be a neighbourhood system. Call a subset $C \subseteq \mathcal{D}$ *consistent* iff every finite subset of C is consistent in $\mathcal{D}$. Give an example where C is a subset with more than two elements, every pair of neighbourhoods in C is consistent, but C is *not* consistent. Show that if C is consistent, then there is a *least* filter $x \in |\mathcal{D}|$ with $C \subseteq x$. Show generally that the *intersection* of any non-empty collection of filters is again a filter.

3.2.26 Exercise 1.19 — positive neighbourhood systems

Define a *positive neighbourhood system* to be a family $\mathcal{D}$ where (ii) of 1.1 is replaced by **(ii')** whenever $X, Y \in \mathcal{D}$, then $X \cap Y \neq \emptyset$ iff $X \cap Y \in \mathcal{D}$. Prove that a positive neighbourhood system is indeed a neighbourhood system in the sense of the earlier definition. Give an example of a neighbourhood system that is *not* positive. (Hint: (suggested by C.A.R. Hoare). Let $\Delta = \mathbf{N} \times \mathbf{N}$, in the plane. Let $\mathcal{D}$ be the family of subsets $X \subseteq \mathbf{N} \times \mathbf{N}$ where all but a finite number of places the *vertical* sections of X are the whole of $\mathbf{N}$ but at the other places the sections are finite and nonempty. Smaller examples are of course possible.)

3.2.28 Exercise 1.21 — complete neighbourhood systems

Work out in greater detail the proof of 1.10. Remark that the neighbourhood system over $|\mathcal{D}|$ so constructed is positive, thereby obtaining in a different way the same kind of conclusion as in 1.20. Show also that the system over $|\mathcal{D}|$ is complete in the sense that every filter is fixed by a unique member of the underlying set. (A filter is *fixed by a point* iff it is the filter of *all* neighbourhoods containing that point.) Remark that a complete system is one where tokens and (partial) elements can always be identified (under a suitable one-one correspondence). Show also that consistency of a set $\{X_i \mid i < n\}$ of neighbourhoods in $\mathcal{D}$ is equivalent to saying

$$\bigcap_{i<n} [X_i] \neq \emptyset.$$

3.2.29 Exercise 1.22 — topology of a domain

(For topologists). Show that the neighbourhoods $[X]$ for $X \in \mathcal{D}$ make $|\mathcal{D}|$ into a topological space where the open subsets $\mathcal{U} \subseteq |\mathcal{D}|$ can be characterized by the following two conditions:

(i) whenever $x \in \mathcal{U}$ and $x \sqsubseteq y \in |\mathcal{D}|$, then $y \in \mathcal{U}$; and

(ii) whenever $x \in \mathcal{U}$, then $[X] \in \mathcal{U}$ for some $X \in x$.

Prove also that the inclusion relation on $|\mathcal{D}|$ can be defined topologically as:

(iii) $x \sqsubseteq y$ iff for all open $\mathcal{U} \subseteq |\mathcal{D}|$, if $x \in \mathcal{U}$ then $y \in \mathcal{U}$.

Is $|D|$ ever a Hausdorff space?
Show that if $(x_n)_{n=0}^{\infty}$ is a sequence of elements of $|D|$ with $x_n \subseteq x_{n+1}$ for all n, then

$$\bigcup_{n=0}^{\infty} x_n$$

is not only in $|D|$ but is a topological limit point of the sequence. Show that any element x is a limit point of the set $\{\uparrow X \mid X \in x\}$. Are there other limit points?

3.2.30 Exercise 1.23 — decidable total elements

Suppose that the neighbourhood system D is countable, say,

$$D = \{X_0, X_1, X_2, \ldots, X_n, \ldots\}.$$

Suppose further that the property of consistency of finite sequences of neighbourhoods is decidable (or "effectively known"). Then the following sequence is well defined:

$$\begin{aligned} Y_0 &= X_0 \\ Y_{n+1} &= X_{n+1}, \text{ if this set is consistent with } Y_0, Y_1, \ldots, Y_n; \\ &= Y_n, \text{ if not.} \end{aligned}$$

Show that $\{Y_0, Y_1, \ldots, Y_n, \ldots\}$ is a total element of $|D|$. (Hint: Show first that $Y_0, Y_1, \ldots, Y_{n-1}$ is consistent for all n.) In such a system show that all filters can be determined by sequences.

3.2.34 Exercise 1.27 — suprema of bounded sets

Further closure properties of domains can be proved for bounded sets. We say $X \subseteq |\mathcal{D}|$ is *bounded* iff for some $y \in |\mathcal{D}|$ we have $x \subseteq y$ for all $x \in X$. This y is called an *upper bound*. We let

$$\bigsqcup X = \bigcap \{y \in |\mathcal{D}| \mid x \subseteq y \text{ all } x \in X\}.$$

Prove that if X is bounded, then $\bigsqcup X$ is the *least upper bound* for X in $|\mathcal{D}|$. Prove also: if $U, V \in \mathcal{D}$ are neighbourhoods, then $\{U, V\}$ is consistent in $\mathcal{D}$ iff $\{\uparrow U, \uparrow V\}$ is bounded in $|\mathcal{D}|$. (That is, boundedness is for elements what consistency is for neighbourhoods.) Prove finally with the aid of 1.18 that $X \subseteq |\mathcal{D}|$ is bounded iff every finite subset of X is bounded.

3.3 Mappings between domains

Dependency diagram. Each box is one item. The arrowhead is on the item that imports. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it is not shown. Blue is a definition, green a proposition, amber an example, red a theorem, and indigo an exercise.

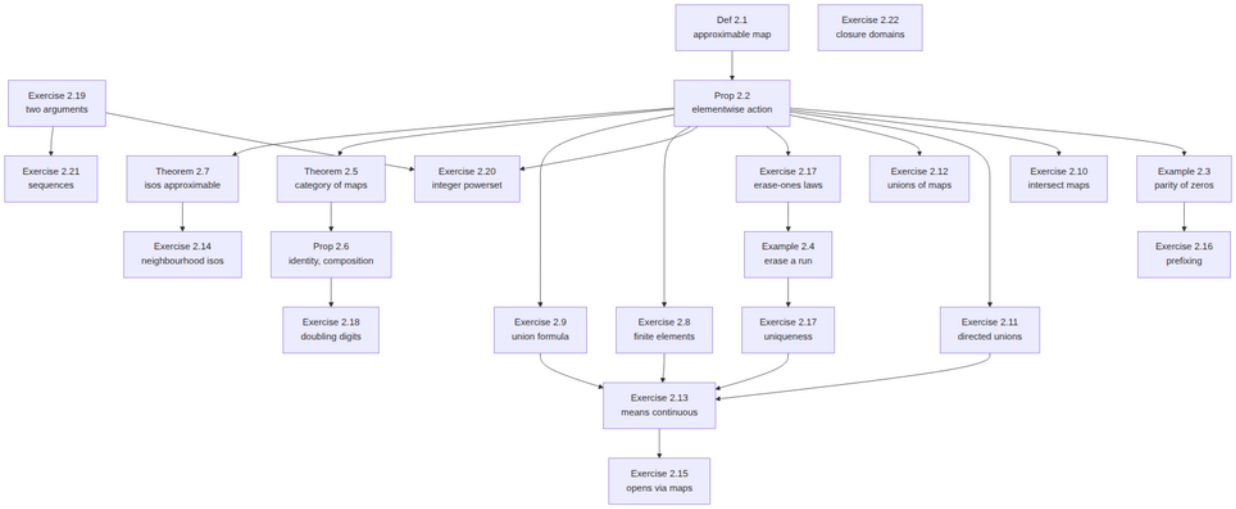

Figure 29: Mappings between domains.

3.3.1 Introduction

LECTURE II MAPPINGS BETWEEN DOMAINS

The elements of a domain are regarded as being specified by approximations: the neighbourhoods. With the idea of approximation as the dominant notion, therefore, it is natural to look for a concept of mapping (transformation of domains) that in some suitable sense preserves the spirit of the approximations. In a 'theory of computability,' where the (finite) approximations to the elements are all we can ever know at one time, the only mappings that can be computed are those that proceed by approximation, somehow passing from the neighbourhoods of one domain over to the neighbourhoods of the other.

Suppose $X \in \mathcal{D}_0$ is given - it is an approximation to certain elements of $|\mathcal{D}_0|$. (More precisely $\uparrow X$ is the approximation in the domain, but it is easier to speak of the neighbourhood X.) What can be said about the approximations of the images of these elements under the mapping we will call f? If X is not a very sharp approximation, then not very much can be said about the image in the other domain $|\mathcal{D}_1|$. Trivially, of course, we can say that Δ_1 is an approximation - because it approximates everything in its domain. Suppose, however, that we could say more. Suppose we could say that both Y and Y' approximate the image of X. If the mapping f is coherent, then it is reasonable to suppose that such a statement would imply that Y and Y' are *consistent* in $\mathcal{D}_1$. But if this is so, then since the two neighbourhoods are meant to cluster around the same images, we can feel some confidence in saying that $Y \cap Y'$ approximates these images. In other words

to specify f we do not supply a unique image of X, but we say which of the $Y \in \mathcal{D}_1$ approximate the (ideal) image. To make this idea work a *monotonicity condition* is also needed since we are trying to express the idea that "if we give at least X as an approximate input to f, then we can expect at least Y as output." Thus,

a mapping is taken as a kind of relation between neighbourhoods.

3.3.2 Definition 2.1 — approximable mapping

DEFINITION 2.1. An *approximable mapping* $f : D_0 \to D_1$ between domains is a binary relation $f \subseteq D_0 \times D_1$ between neighbourhoods such that

(i) $\Delta_0 f \Delta_1$;

(ii) $X f Y$ and $X f Y'$ always imply $X f (Y \cap Y')$;

(iii) $X f Y$, $X' \subseteq X$, and $Y \subseteq Y'$ always imply $X' f Y'$. □

Condition (i) we have already discussed; in a sense it means "ask me no questions and I shall tell you no lies." In other words "zero input can expect at least zero output." The other conditions are compatible with having

$$f = \{\langle X, \Delta_1 \rangle \mid X \in D_0\};$$

that is, f might be the least informative relation and nothing more. But if it is more, then (ii) is, as we explained, a consistency condition. To explain monotonicity in (iii), suppose a mapping relationship is already known, $X f Y$, say. If we *improve* the accuracy of X to $X' \subseteq X$ and if we *degrade* the accuracy of Y to $Y' \supseteq Y$, then we can still assert $X' f Y'$ since this relationship is *less informative* than the former relationship, which was already known. Thus, we see that conditions (i)–(iii) are all reasonably argued as necessary.

One indication that the conditions of 2.1 are sufficient for a definition is that they are exactly what we need to show that f as a neighbourhood relation determines an equivalent elementwise mapping from $|D_0|$ into $|D_1|$. (Owing to the equivalence, we use the same symbol f for both.)

3.3.3 Proposition 2.2 — elementwise action

PROPOSITION 2.2. Given neighbourhood systems D_0 and D_1, an approximable mapping $f : D_0 \to D_1$ always determines a function $f : |D_0| \to |D_1|$ between domains by virtue of the formula:

(i) $f(x) = \{Y \in D_1 \mid \exists X \in x.\ X f Y\}$

for all $x \in |D_0|$. Conversely, this function uniquely determines
the original relation by the equivalence:

(ii) $X f Y$ iff $Y \in f(\uparrow X)$

for all $X \in D_0$ and $Y \in D_1$. Approximable functions are always monotone in the following sense:

(iii) $x \subseteq y$ always implies $f(x) \subseteq f(y)$,

for $x, y \in |D_0|$; moreover two approximable functions $f : D_0 \to D_1$ and $g : D_0 \to D_1$ are identical as relations iff

(iv) $f(x) = g(x)$, for all $x \in |D_0|$.

Proof: The argument that formula (i) always gives us $f(x) \in |D_1|$ when $x \in |D_0|$ can be safely left to the reader. Note, however, that all the conditions of 2.1 are required to show this. As for (ii), the implication from left to right follows directly from (i) because $X \in \uparrow X$. In the other direction $Y \in f(\uparrow X)$ means that $Z f Y$ holds for some $Z \in \uparrow X$. But from $X \subseteq Z$ it follows that $X f Y$, as we wished.

To prove monotonicity, assume $x \subseteq y$. Now $X \in x$ and $X f Y$ always imply $X \in y$ and $X f Y$. This means $Y \in f(x)$ always implies $Y \in f(y)$; that is, $f(x) \subseteq f(y)$.

Finally, to check that (iv) means $f = g$ as relations, all that has to be remarked that this follows from formulae (i) and (ii). □

Note that the right-hand side of (ii) can be written:

$$\uparrow Y \subseteq f(\uparrow X),$$

which can be read as saying that the partial element determined by the neighbourhood Y approximates the function value at the element determined by X. This precise relationship of course fits the informal discussion of mapping given earlier. Indeed whenever $x \in [X]$ and $X f Y$ hold, then $f(x) \in [Y]$ always

follows, which is another way to construe the mapping character of f. Some examples of mappings are now called for.

3.3.4 Example 2.3 — parity of leading zeros

EXAMPLE 2.3. Let T be the neighbourhood system of the two-token domain of Example 1.2. To avoid confusion with some other domains, we will call the two total elements of $|T|$ respectively true and false. There is only one other finite element here, namely $\perp =$ undefined. We often use these elements as indicators of results: true indicates a positive outcome; false, a negative outcome; and $\perp$ indicates that there is not enough information to decide the outcome totally.

Let B be the system for the binary tree as in the last chapter. What we wish to define is an approximable mapping $f : B \to T$. The intuitive idea of the mapping we have in mind is that the binary sequence is being read from left to right, and we are counting the number of 0's seen before the first 1 is encountered. We then test the parity of this count; if it is even, the output is true; if not, false. Using a suggestive informal notation with three dots, some results of the function that does the counting and testing can be written as:

$$f(0000101\ldots) = \text{true}$$
$$f(1101110\ldots) = \text{true}$$
$$f(0111011\ldots) = \text{false}$$
$$f(0000000\ldots) = \perp .$$

The last equation is necessary, because 0000000 as a partial element cannot be counted as either even or odd since it can have inconsistent extensions:

$$0000000\ \perp \sqsubseteq 00000001\ \perp$$
$$0000000\ \perp \sqsubseteq 000000000001\ \perp .$$

So, as far as f is concerned, a plain string of 0's is indefinite. The same answer holds if the 0's go on infinitely.

To be more precise we want

$$f(0^n 1\ \perp) = \text{true} \quad \text{if } n \text{ is even;}$$
$$= \text{false} \quad \text{if } n \text{ is odd.}$$

As a binary relation $f \subseteq B \times T$ we will have

$X f Y$ iff $Y \in \perp$ or $X \sqsubseteq 0^n 1\Delta$ for some $n \in \mathbf{N}$ and either n is even and $Y \in$ true or n is odd and $Y \in$ false.

It should be checked that 2.1(i)–(ii) are satisfied. □

3.3.5 Example 2.4 — erase a run of ones

EXAMPLE 2.4. Let us briefly describe an approximable mapping $g : B \to B$. Informally, g can be said to "read a sequence from left to right and eliminate the first consecutive run of 1's while copying all the other digits as read." We will have

$$g(0^n 1^k 0x) = 0^{n+1}x$$

provided $k > 0$. (Here 1^k means a string of 1's of length k.) However, if 1^∞ is the infinite sequences of 1's, then

$$g(1^\infty) = \bot, \text{ and}$$
$$g(0^n 1^\infty) = 0^n.$$

This example is instructive, since it shows that a non-trivial mapping can transform a total element into a partial element. □

Aside from our being able to define particular functions outright, we can combine functions in many different ways; the idea of composition is probably the most basic scheme of combination, and there is a technical name for a family of structures with mappings that can be so combined.

3.3.6 Theorem 2.5 — category of approximable maps

THEOREM 2.5. The class of neighbourhood systems and approximable mappings form a *category*, where the identity mapping $I_D : D \to D$ relates $X, Y \in D$ as follows:

(i) $X\ I_D\ Y$ iff $X \subseteq Y$.

If $f : D_0 \to D_1$ and $g : D_1 \to D_2$ are given, then the *composition* $g \circ f : D_0 \to D_2$ relates $X \in D_0$ and $Z \in D_2$ as follows:

(ii) $X\ g \circ f\ Z$ iff $\exists Y \in D_1.\ X\ f\ Y$ and $Y\ g\ Z$.

Proof: (We may use MacLane [1971] as the standard reference on category theory, but we require hardly more than the basic definitions at this stage.) To check that we have a category, we need to know that the identity and composition maps really are maps in the category and that certain identity and associative laws hold. Now it is obvious that I_D satisfies 2.1 (i)-(iii). Moreover if $f : D_0 \to D_1$, all we have to prove is:

$$f \circ I_{D_0} = I_{D_1} \circ f = f$$

Checking one of these equations is enough. Thus, for $X \in D_0$ and $Z \in D_1$ we find

$$\begin{aligned} X\ f \circ I_{D_0}\ Z &\text{ iff } \exists Y \in D_0.\ X \subseteq Y \text{ and } Y\ f\ Z \\ &\text{iff } X\ f\ Z. \end{aligned}$$

So, f and $f \circ I_{D_0}$ are the same mapping.

Suppose now that $f : D_0 \to D_1$ and $g : D_1 \to D_2$. We have to verify that $g \circ f$ is an approximable mapping. First off, there is no trouble in seeing that $\Delta_0\ g \circ f\ \Delta_2$ holds. Next, suppose that $X\ g \circ f\ Z$ and $X\ g \circ f\ Z'$ hold. Then we have $X\ f\ Y$ and $Y\ g\ Z$ for some choice of $Y \in D_1$. Also $X\ f\ Y'$ and $Y'\ g\ Z'$ hold for some choice of $Y' \in D_1$. By 2.1 (ii) it follows that $X\ f\ (Y \cap Y')$. Since $Y \cap Y' \subseteq Y$, we conclude $(Y \cap Y')\ g\ Z$ by 2.1 (iii); similarly $(Y \cap Y')\ g\ Z'$. Invoking 2.1 (ii) again, we obtain $(Y \cap Y')\ g\ (Z \cap Z')$, and $X\ g \circ f\ (Z \cap Z')$ is proved.

Suppose finally that $X' \subseteq X$, $X\ g \circ f\ Z$, and $Z \subseteq Z'$. Now $X\ f\ Y$ and $Y\ g\ Z$ for some $Y \in D_1$. But then $X'\ f\ Y$ holds; for a similar reason $Y\ g\ Z'$ holds also. Therefore, $X'\ g \circ f\ Z'$ is established, which means that we have checked 2.1 (iii) for $g \circ f$ and have completed the proof that $g \circ f : D_0 \to D_2$.

The verification of associativity is a purely logical deduction. Thus suppose that in addition to f and g we have $h : D_2 \to D_3$. If $X \in D_0$ and $W \in D_3$ we find

$$\begin{aligned} X\ h \circ (g \circ f)\ W &\text{ iff } \exists Z \in D_2.\ X\ g \circ f\ Z \text{ and } Z\ h\ W \\ &\text{iff } \exists Z \in D_2\ \exists Y \in D_1.\ X\ f\ Y \text{ and } Y\ g\ Z \text{ and } Z\ h\ W \\ &\text{iff } \exists Y \in D_1\ \exists Z \in D_2.\ X\ f\ Y \text{ and } Y\ g\ Z \text{ and } Z\ h\ W \\ &\text{iff } \exists Y \in D_1.\ X\ f\ Y \text{ and } Y\ (h \circ g)\ W \\ &\text{iff } X\ (h \circ g) \circ f\ W. \end{aligned}$$

So, as relations, $h \circ (g \circ f) = (h \circ g) \circ f$. $\square$

It may seem as though we have, in the definition of composition, written things backwards. But the reason is that when mappings are taken as elementwise functions, then the order is preserved in expressions involving the usual function value notation. We have, for example:

3.3.7 Proposition 2.6 — identity and composition

PROPOSITION 2.6. Given $f : D_0 \to D_1$ and $g : D_1 \to D_2$, the following equations hold:

(i) $I_{D_0}(x) = x$, and

(ii) $(g \circ f)(x) = g(f(x))$,

for all $x \in |D_0|$. $\square$

The proof is not troublesome and is left as an exercise. In technical language the result shows that the category defined in Theorem 2.5 is equivalent to a "concrete category" of sets and functions, namely the domains and elementwise transformations of 2.2.

Toward the end of the last lecture (see 1.9) we promised to show that isomorphisms of domains always come from approximable mappings, and this we now do. It means that the category contains all the isomorphisms it should have.

3.3.8 Theorem 2.7 — isomorphisms are approximable

THEOREM 2.7. Every isomorphism between domains results from an approximable mapping between the neighbourhood systems. Moreover, finite elements are always transformed into finite elements.

Proof: Suppose that $f : |D_0| \to |D_1|$ is a one-one, inclusion-preserving function defined on elements, where the range of the function is the whole of $|D_1|$, of course. Taking the hint from 2.2, there is only one way we could define a neighbourhood mapping; namely, we consider the relation $Y \in f(\uparrow X)$ for $X \in D_0$ and $Y \in D_1$. What has to be shown is that this is an approximable mapping which determines the original function via the formula 2.2 (i).

The first part is easy; indeed, there is a general result that monotone functions on finite elements of one domain to arbitrary elements of another domain always determine approximable mappings (cf. Exercise 2.8). What remains, then, is to show that the relation re-defines the function. This comes down to showing that for $x \in |D_0|$

$$f(x) = \{Y \in D_1 \mid \exists X \in x.\, Y \in f(\uparrow X)\}.$$

Consider the right-hand side of this equation: it is a filter. (This either can be proved directly or Exercise 2.11 can be used.) Because f is an onto-function, we can call the right-hand side $f(x')$ for some $x' \in |D_0|$. But since $X \in x$ implies $\uparrow X \subseteq x$ and $f(\uparrow X) \subseteq f(x)$, the right-hand side is included in the left-hand side. In other words $f(x') \subseteq f(x)$. But, since f is an isomorphism, $x' \subseteq x$ follows.

In the other direction, if $X \in x$, then $f(\uparrow X) \subseteq f(x')$ holds by definition, so $\uparrow X \subseteq x'$. This implies $X \in x'$; and, as X is arbitrary, $x \subseteq x'$. So $x = x'$, and $f(x) = f(x')$ as desired.

Finally, consider any finite element $\uparrow X \in |D_0|$, where $X \in D_0$. What we have to show is that $f(\uparrow X)$ is finite in $|D_1|$. Because f is an isomorphism, we can associate uniquely to every $Y \in f(\uparrow X)$ an element $y_Y \subseteq\uparrow X$ in $|D_0|$ where $f(y_Y) =\uparrow Y$. (Just apply the inverse of the function f.) Define

$$z = \bigcup\{y_Y \mid Y \in f(\uparrow X)\}.$$

Because $Y' \subseteq Y$ always implies $y_{Y'} \subseteq y_Y$ and each $y_Y \in |D_0|$, it is easy to show z is a filter and hence is in $|D_0|$ also (cf. Exercise 2.11). Because each $y_Y \subseteq\uparrow X$, then $z \subseteq\uparrow X$, too. But each $y_Y \subseteq z$, so $\uparrow Y = f(y_Y) \subseteq f(z)$ and hence $Y \in f(z)$. As this holds for all $Y \in f(\uparrow X)$, the inclusion $f(\uparrow X) \subseteq f(z)$ follows, as well as $\uparrow X \subseteq z$. Therefore, $z =\uparrow X$ and so $X \in z$. But then $X \in y_Y$ for some $Y \in f(\uparrow X)$, by definition of z. Since $\uparrow X \subseteq y_Y$, we obtain $f(\uparrow X) \subseteq\uparrow Y$, but of course the opposite inclusion is also true from the choice of Y. This means that $f(\uparrow X) =\uparrow Y$ is finite in $|D_1|$ as claimed. We can apply the same argument to the inverse function; and, thus, the finite elements of $|D_0|$ and $|D_1|$ are in a one-one inclusion-preserving correspondence under the isomorphism. □

3.3.13 Exercise 2.11 — directed unions of elements

Let $(I, \leq)$ be a non-empty abstract partially ordered set; suppose it is directed in the sense that whenever $i, j \in I$, then $i \leq k$ and $j \leq k$ for some $k \in I$. Suppose that $a : I \to |D|$ is such that

$$i \leq j \text{ implies } a_i \subseteq a_j$$

for all $i, j \in I$. Prove that

$$\bigcup\{a_i \mid i \in I\}$$

is always a filter in $|D|$. (Note the ways this lemma could be used in the proof of 2.7; but be careful in defining the partially ordered set and do not confuse $\subseteq$ and $\supseteq$.) In words we could say that the domain of filters is closed under directed unions. Prove also that if $f : D \to D'$ is an approximable mapping, then for any directed union

$$f(\bigcup\{a_i \mid i \in I\}) = \bigcup\{f(a_i) \mid i \in I\};$$

that is, approximable mappings always preserve directed unions. If an elementwise function preserves directed unions, must it come from an approximable mapping? (Hint: Invoke 2.9.)

3.3.15 Exercise 2.13 — approximable means continuous

(For topologists.) Recall Exercise 1.22 where it was shown that any domain $|D|$ is a topological space. Prove from Exercise 2.9 that the functions $f : |D_0| \to |D_1|$ determined by approximable mappings are exactly *the continuous functions between these spaces.* (Hint: To prove continuity, remark that by 2.9

$$f^{-1}[Y] = \bigcup\{[X] \mid Y \in f(\uparrow X)\};$$

hence, the inverse image of any open set is open. In the other direction, suppose that $f : |D_0| \to |D_1|$ is topologically continuous. Argue that for all $x \in |D_0|$ and all open subsets $U \subseteq |D_1|$ we have

$$f(x) \in U \text{ iff } \exists X \in x.\ f(\uparrow X) \in U.$$

This holds because an open subset of $|D_0|$ is always a union of basic open subsets of the form $[X']$ for $X \in D_0$ and because

$$x = \bigcup \{\uparrow X \mid X \in x\}$$

for all $x \in |D_0|$.)

3.3.16 Exercise 2.14 — isomorphisms of neighbourhoods

Let $f : |D_0| \to |D_1|$ be an isomorphism between domains. Let $\varphi : D_0 \to D_1$ be the one-one correspondence between neighbourhoods provided by Theorem 2.7 where

$$f(\uparrow X) = \uparrow \varphi(X)$$

for all $X \in D_0$. Show that the approximable mapping determined by f is just the relationship $\varphi(X) \subseteq Y$. In addition prove that if $X, X' \in D_0$ are consistent, then

$$\varphi(X \cap X') = \varphi(X) \cap \varphi(X').$$

Remark that the isomorphisms between domains correspond exactly to the isomorphisms between neighbourhood systems (in the sense of one-one inclusion preserving correspondences).

3.3.17 Exercise 2.15 — opens classified by maps

(For topologists.) Consider the one-token system with

$$\mathcal{O} = \{\{0\}, \emptyset\}.$$

We can regard $|\mathcal{O}|$ as having just two finite elements $\bot$ (bottom) and $\top$ (top), where $\bot \sqsubseteq \top$. For any system D, show that the open subsets U of $|D|$ are in a one-one correspondence with the approximable mappings $f : D \to \mathcal{O}$, where the correspondence is given by the equation

$$U = \{x \in |D| \mid f(x) = \top\}.$$

What are the open subsets of $|\mathcal{O}|$? of $|\mathbb{T}|$? of $|\mathbb{B}|$?

3.3.24 Exercise 2.21 — finite and infinite sequences

The system $\mathcal{B}$ of 2.3 has as its total elements only the infinite sequences. Modify the construction of $\mathcal{B}$ to another neighbourhood system $\mathcal{C}$ which has *both* the finite and infinite sequences as total elements. (Hint: $\mathcal{B} \subseteq \mathcal{C}$.) Show that there is an approximable map xy on elements naturally extending ordinary juxtaposition of sequences. (Hint: Write 01001 for a *total* finite sequence and $01001 \perp$ for the corresponding finite partial element. Remember to distinguish between Λ (the total empty sequence) and $\perp$ (the undefined sequence). The definition should work out so that if x is an infinite sequence (hence, total), then $xy = x$ for all y. What will xy equal if x is not total? In other words, the construction possesses a rather strong left-to-right bias.)

3.3.25 Exercise 2.22 — domains from closure properties

(For set theorists). We have remarked in Exercise 1.18 and in Exercise 2.11 that any domain $|D|$, as a family of sets (in fact, a family of subsets of the set D itself), is closed under the intersection of an arbitrary non-empty sub family and under the union of any directed sub family. For those familiar with the subject matter, the example of the (proper) ideals of a commutative ring (with unit) is also seen to be such a family. What is the abstract situation? Let $\mathbf{C}$ be *any* family of sets with these closure properties. It is to be shown that $\mathbf{C}$ is inclusion-isomorphic to a domain. (Hint: Let Δ be the set of finite sets included in sets in $\mathbf{C}$. For $F \in \Delta$, define its "closure" by the equation:

$$\overline{F} = \bigcap \{X \in \mathbf{C} \mid F \subseteq X\}.$$

Every $\overline{F} \in \mathbf{C}$, and these will prove to be the "finite" elements of $\mathbf{C}$. The neighbourhood system $\mathcal{D}$ over Δ can be taken to be the sets of the form

$$C(F) = \{G \in \Delta \mid F \subseteq \overline{G}\}$$

for $F \in \Delta$. Notice that for all $X \in \mathbf{C}$

$$X = \bigcup\{\overline{F} \mid F \subseteq X \text{ and } F \in \Delta\}.$$

)

Check that approximable functions on these families are just those preserving directed unions.

LECTURE III

DOMAIN CONSTRUCTS

Having now seen a number of domains presented through their neighbourhood systems, we need next to introduce general constructs for forming new domains from old. There are an unlimited number of such constructs (technically called *functors*), but we have time only to single out a few of the more important ones. Outstanding among all of them is the notion of product of systems, which in our chosen category has all the expected properties. For the time being in order to simplify notation we assume of the underlying sets Δ_0 and Δ_1 of systems $\mathcal{D}_0$ and $\mathcal{D}_1$ that they are disjoint. There is no loss of generality as $\mathcal{D}_1$ can always be replaced by an isomorphic system disjoint from $\mathcal{D}_0$ in the required sense.

3.4.1 Introduction

LECTURE III

DOMAIN CONSTRUCTS

Having now seen a number of domains presented through their neighbourhood systems, we need next to introduce general constructs for forming new domains from old. There are an unlimited number of such constructs (technically called *functors*), but we have time only to single out a few of the more important ones. Outstanding among all of them is the notion of product of systems, which in our chosen category has all the expected properties. For the time being in order to simplify notation we assume of the underlying sets Δ_0 and Δ_1 of systems $\mathcal{D}_0$ and $\mathcal{D}_1$ that they are disjoint. There is no loss of generality as $\mathcal{D}_1$ can always be replaced by an isomorphic system disjoint from $\mathcal{D}_0$ in the required sense.

3.4.2 Definition 3.1 — product of systems

DEFINITION 3.1. Let neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$ be given over disjoint sets Δ_0 and Δ_1. The *product system* over $\Delta_0 \cup \Delta_1$ is defined by:

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{X \cup Y \mid X \in \mathcal{D}_0 \text{ and } Y \in \mathcal{D}_1\}.$$

For elements $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$ we also define:

$$\langle x, y \rangle = \{X \cup Y \mid X \in x \text{ and } Y \in y\}.$$

3.4.3 Proposition 3.2 — elements of a product

PROPOSITION 3.2. The construct $\mathcal{D}_0 \times \mathcal{D}_1$ always gives a neighbourhood system where for elements $x, x' \in |\mathcal{D}_0|$ and $y, y' \in |\mathcal{D}_1|$ we have

(i) $\langle x, y \rangle \subseteq \langle x', y' \rangle$ iff $x \subseteq x'$ and $y \subseteq y'$.

Moreover, there is a one-one correspondence between the elements of $|\mathcal{D}_0 \times \mathcal{D}_1|$ and pairs of elements of $|\mathcal{D}_0|$ and $|\mathcal{D}_1|$ since all elements of $|\mathcal{D}_0 \times \mathcal{D}_1|$ are of the form $\langle x, y \rangle$.

Proof: Owing to the disjointness of Δ_0 and Δ_1, we note that for $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$ we have

$$(1)\ X \cup Y \subseteq X' \cup Y' \text{ iff } X \subseteq X' \text{ and } Y \subseteq Y'.$$

Thus, $\{X \cup Y, X' \cup Y'\}$ is consistent in $\mathcal{D}_0 \times \mathcal{D}_1$ iff $\{X, X'\}$ is consistent in $\mathcal{D}_0$ and $\{Y, Y'\}$ is consistent in $\mathcal{D}_1$. In the consistent case we find

$$(2) \qquad (X \cup Y) \cap (X' \cup Y') = (X \cap X') \cup (Y \cap Y'),$$

and so $\mathcal{D}_0 \times \mathcal{D}_1$ is closed under consistent intersection. As $\Delta_0 \cup \Delta_1 \in \mathcal{D}_0 \times \mathcal{D}_1$, it is certainly a neighbourhood system.

It is easy to check by the previous calculations that $\langle x, y\rangle \in |\mathcal{D}_0 \times \mathcal{D}_1|$ if $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$. The proof of 3.2(i) follows directly from the definition and (1).

Suppose $z \in |\mathcal{D}_0 \times \mathcal{D}_1|$. Define as a temporary notation:

$$z_0 = \{X \in \mathcal{D}_0 \mid X \cup \Delta_1 \in z\}, \quad \text{and} \quad z_1 = \{Y \in \mathcal{D}_1 \mid \Delta_0 \cup Y \in z\}.$$

Clearly, both $z_0 \in |\mathcal{D}_0|$ and $z_1 \in |\mathcal{D}_1|$. In view of the formula

$$(3) \qquad (X \cup \Delta_1) \cap (\Delta_0 \cup Y) = X \cup Y,$$

we can calculate that

$$z = \langle z_0, z_1\rangle.$$

Moreover, if $z = \langle x, y\rangle$, then $\langle x, y\rangle_0 = x$ and $\langle x, y\rangle_1 = y$.

The one-one correspondence required is thus established. □

There is more going on in the proof of 3.2 than just a one-one correspondence between elements and pairs. The extra information is best formalized by introducing a notation for mappings.

3.4.4 Definition 3.3 — projection mappings

DEFINITION 3.3. *Projection mappings*

$$p_0 : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_0 \quad \text{and} \quad p_1 : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_1$$

are defined as relations where

$$(X \cup Y)\ p_0\ X' \text{ iff } X \subseteq X', \quad \text{and} \quad (X \cup Y)\ p_1\ Y' \text{ iff } Y \subseteq Y'$$

hold for all $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$. Given $f : \mathcal{D}_2 \to \mathcal{D}_0$ and $g : \mathcal{D}_2 \to \mathcal{D}_1$, the *paired mapping*

$$\langle f, g \rangle : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$$

is defined as a relation where

$$Z\ \langle f, g \rangle\ (X \cup Y) \text{ iff } Z\ f\ X \text{ and } Z\ g\ Y$$

holds for all $X \in \mathcal{D}_0$, $Y \in \mathcal{D}_1$, and $Z \in \mathcal{D}_2$. □

3.4.5 Proposition 3.4 — pairing and projections

PROPOSITION 3.4. The mappings p_0, p_1 and $\langle f, g\rangle$ are approximable mappings, provided f and g are, and we have:

(i) $p_0 \circ \langle f, g\rangle = f$ and $p_1 \circ \langle f, g\rangle = g$.

Moreover, for $z \in |\mathcal{D}_0 \times \mathcal{D}_1|$, we have:

(ii) $p_0(z) = z_0$ and $p_1(z) = z_1$,

in the notation of the proof of 3.2. Further if $h : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$ is any approximable mapping, then

(iii) $h = \langle p_0 \circ h, p_1 \circ h\rangle$.

Moreover, for all $w \in |\mathcal{D}_2|$, we have:

(iv) $\langle f, g\rangle(w) = \langle f(w), g(w)\rangle$,

where again on the right-hand side the notation of the proof of 3.2 is used. □

The proof of this result is left as an exercise. Note the consequence that there is a one-one correspondence between pairs of approximable mappings $f : \mathcal{D}_2 \to \mathcal{D}_0$ and $g : \mathcal{D}_2 \to \mathcal{D}_1$ and mappings $h : \mathcal{D}_2 \to \mathcal{D}_0 \times \mathcal{D}_1$. It is clear that we generalize all this to products

$$\mathcal{D}_0 \times \mathcal{D}_1 \times \cdots \times \mathcal{D}_{n-1}$$

of several systems.

The product construct also neatly explains functions of several variables. In Exercise 2.19 we used the informal notation

$$f : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2$$

and suggested regarding f as a ternary relation

$$X, Y \; f \; Z.$$

But now with $\mathcal{D}_0 \times \mathcal{D}_1$ given an independent meaning, all we have to do is to regard f as a binary relation with

$$(X, Y) \; f \; Z$$

equivalent to the old relationship. We can also employ an element-wise notation as in $f(\langle x, y \rangle)$, which can more easily be written $f(x, y)$. Similar remarks apply to functions of more than two arguments.

We have discussed several times what it means for a function $f(x)$ to come from an approximable mapping. It is interesting to ask the analogous question for functions of several arguments.

3.4.6 Theorem 3.5 — separate approximability

THEOREM 3.5. An elementwise function

$$f : |D_0 \times D_1| \to |D_2|$$

of two arguments comes from an approximable mapping iff for each fixed $a \in |D_0|$ and each fixed $b \in |D_1|$ the transformations

$$x \mapsto f(x, b) \quad \text{and} \quad y \mapsto f(a, y)$$

come from approximable mappings of one argument.

Proof: As this is the first time we have had to deal with constants in functions, a lemma is useful.

3.4.7 Lemma 3.6 — constant functions

LEMMA 3.6. Given $b \in |D_1|$, the constant function

$$b : |D_0| \to |D_1|$$

where $b(x) = b$ for all $x \in |D_0|$, comes from the approximable mapping such that

$$X \; b \; Y \quad \text{iff} \quad Y \in b,$$

for all $X \in D_0$ and $Y \in D_1$. □

There is no real confusion here in using "b" both for function and value. Returning, then, to the proof of 3.5, we see that the reason that $x \mapsto f(x, b)$ comes from an approximable mapping is that the mapping in question is the composition of two approximable mappings, namely $f \circ \langle I_{D_0}, b \rangle$. Clearly we can interchange the rôles of D_0 and D_1 to get at $y \mapsto f(a, y)$.

Conversely, assume that both these functions come from approximable mappings no matter the choice of a and b. Clearly the mapping to determine f is the relation from $X \cup Y$ to Z where

$$Z \in f(\uparrow X, \uparrow Y) = f(\uparrow (X \cup Y)).$$

To prove that this determines f we calculate by the formula of Exercise 2.9:

$$\begin{aligned} f(x, y) &= \bigcup \{ f(\uparrow X, y) \mid X \in x \} \\ &= \bigcup \{ \bigcup \{ f(\uparrow X, \uparrow Y) \mid Y \in y \} \mid X \in x \} \\ &= \bigcup \{ f(\uparrow X, \uparrow Y) \mid X \in x \text{ and } Y \in y \} \\ &= \bigcup \{ f(\uparrow (X \cup Y)) \mid (X \cup Y) \in \langle x, y \rangle \}. \end{aligned}$$

And, again by 2.9, this is what was needed. □

Said more informarily, a function of several arguments is approximable in all the variables *jointly* if it is approximable in each of the variables *separately*.

The type of argument used in 3.5 in the first half of the proof also provides a generalization of 2.6 to functions of several arguments. When we form a function like

$$f(g(x, z, \ldots), h(y, x, \ldots), k(z, w, \ldots), \ldots)$$

from given functions $f, g, h, k, \ldots$; we call the process *substitution*.

3.4.8 Proposition 3.7 — closure under substitution

PROPOSITION 3.7. The functions of several arguments between domains coming from approximable mappings are closed under substitution.

Proof: An example will establish the method. Suppose there are four variables involved taking values in domains provided by systems D_0, D_1, D_2, D_3. We might have a substitution like:

$$f(g(x_0, x_1), h(x_1, x_2), k(x_3, x_0, x_2)).$$

Here it might be that the values of the functions inside come from quite other systems; for instance,

$$k : D_3 \times D_0 \times D_2 \to D_4$$

might be possible. By using projections

$$p_i : D_0 \times D_1 \times D_2 \times D_3 \to D_i,$$

where $i < 4$, we can assure that we have several functions all on the same product; thus,

$$k \cdot \langle p_3, p_0, p_2 \rangle : D_0 \times D_1 \times D_2 \times D_3 \to D_4.$$

Now no matter on what domains f is defined, the following composition makes sense:

$$f \circ \langle g \circ \langle p_0, p_1 \rangle, h \circ \langle p_1, p_2 \rangle, k \circ \langle p_3, p_0, p_2 \rangle \rangle;$$

and in fact this is the desired function. Writing it this way makes it clear that the function comes from an approximable mapping: we apply 3.3 (generalized, of course, to products with several terms) to construe the parts between brackets $\langle$ and $\rangle$ as approximable mappings, and then by this trick the composition $\circ$ is the ordinary composition of 2.6. □

It has to be admitted that there is a slight point overlooked in forming products like $D \times D$ with two identical domains. This is discussed in Exercise 3.14, invoking explicit isomorphisms.

The construct that makes the whole theory of domains work so smoothly is the function-space construct: it is possible to regard functions as *objects* which form a domain. Look back at Definition 2.1 and compare it with the original definition of element in 1.6. There are obvious formal similarities, except that filters are sets of neighbourhoods and mappings are sets of pairs of neighbourhoods (relations). But as we saw in 1.10 it is possible to turn the filters into tokens via a simple definition of neighbourhood. We apply the same kind of definition to the mappings.

3.4.9 Definition 3.8 — function space

DEFINITION 3.8. Given neighbourhood systems D_0 and D_1, the *function space* $(D_0 \to D_1)$ is the system whose set of tokens is the set of approximable mappings of Definition 2.1 and whose neighbourhoods are finite non-empty intersections of sets of the form

$$[X, Y] = \{f : D_0 \to D_1 \mid X f Y\},$$

where $X \in D_0$ and $Y \in D_1$. □

We have been calling our mappings "approximable" for a long time now without saying exactly how they can be approximated! Definition 3.8 supplies the missing key, because once a domain has been defined, then the general theory gives an explicit meaning to the word approximation. We still have to verify, however, that the mappings do correspond to the elements of the domain.

3.4.10 Proposition 3.9 — consistent step neighbourhoods

PROPOSITION 3.9. Let neighbourhoods $X_i \in D_0$ and $Y_i \in D_1$ be given for $i < n$. Then the set of $[X_i, Y_i]$ for $i < n$ is consistent in $(D_0 \to D_1)$ iff the following condition holds:

(i) whenever $I \subseteq \{0, 1, \ldots, n-1\}$ and $\{X_i \mid i \in I\}$ is consistent in D_0, then $\{Y_i \mid i \in I\}$ must be consistent in D_1.

Moreover, when consistency holds, the least approximable mapping f_0 belonging to the intersection of the $[X_i, Y_i]$ is defined by:

(ii) $X f_0 Y$ iff $\bigcap\{Y_i \mid X \subseteq X_i\} \subseteq Y$ for $X \in D_0$ and $Y \in D_1$.

Proof: Suppose the $[X_i, Y_i]$ are consistent in $(D_0 \to D_1)$. Since the function space is being defined outright as a positive system, consistency means

$$f \in \bigcap\{[X_i, Y_i] \mid i < n\}$$

for some $f : D_0 \to D_1$. Now, with f in hand, let us check condition (i). Suppose $\{X_i \mid i \in I\}$ is consistent. This means

$$x \in \bigcap\{[X_i] \mid i \in I\}$$

for some $x \in |D_0|$. Suppose $i \in I$, so $x \in [X_i]$. Since $X_i f Y_i$ holds, $f(x) \in [Y_i]$. This means, therefore, that

$$f(x) \in \bigcap\{[Y_i] \mid i \in I\},$$

and so $\{Y_i \mid i \in I\}$ is consistent.

For the converse, suppose (i) is the case. We take (ii) as the definition of a mapping and remark that for an arbitrary $X \in D_0$, the set $\{X_i \mid X \subseteq X_i\}$ is automatically consistent in D_0. By our assumption, the set $\{Y_i \mid X \subseteq X_i\}$ is therefore consistent. This means that

$$\bigcap\{Y_i \mid X \subseteq X_i\} \in D_1.$$

(Keep in mind that i is restricted to those $i < n$, and there are only finitely many neighbourhoods being considered here.) It is thus almost immediate that the relation f_0 defined by (ii) satisfies conditions of 2.1 and so is an approximable mapping $f_0 : D_0 \to D_1$. By construction

$$X_i f_0 Y_i$$

holds trivially for all $i < n$; therefore,

$$f_0 \in \bigcap\{[X_i, Y_i] \mid i < n\}$$

and the desired consistency is established.

Finally suppose that f is any mapping in the neighbourhood under discussion; this means $X_i f Y_i$ holds for all $i < n$. Suppose $X f_0 Y$ holds. We have for $X \subseteq X_i$, $X f Y_i$; so

$$X f \bigcap \{Y_i \mid X \subseteq X_i\} \subseteq Y.$$

Thus, $X f Y$ follows; hence, as relations, $f_0 \subseteq f$. In other words f_0 is the minimal element of the neighbourhood. □

We note that, as a consequence of what we have just proved, when the neighbourhood is consistent, then

$$\bigcap \{[X_i, Y_i] \mid i < n\} \subseteq [X, Y]$$

is exactly equivalent to

$$\bigcap \{Y_i \mid X \subseteq X_i\} \subseteq Y.$$

Note also that a single neighbourhood $[X_0, Y_0]$ is always consistent since it contains the *constant mapping* k where

$$X k Y \text{ iff } Y_0 \subseteq Y,$$

for all $X \in \mathcal{D}_0$ and $Y \in \mathcal{D}_1$. Some other simple observations about these neighbourhoods are just translations of the conditions of Definition 2.1:

$$[\Delta_0, \Delta_1] = |\mathcal{D}_0 \to \mathcal{D}_1|;$$

$$[X, Y] \cap [X, Y'] = [X, Y \cap Y']; \text{ and}$$

$$X' \subseteq X \text{ and } Y \subseteq Y' \text{ imply } [X, Y] \subseteq [X', Y'],$$

for all $X, X' \in \mathcal{D}_0$ and $Y, Y' \in \mathcal{D}_1$. We are now ready to prove the main result about the construct.

3.4.11 Theorem 3.10 — elements are mappings

THEOREM 3.10. Given neighbourhood systems $\mathcal{D}_0$ and $\mathcal{D}_1$, the function space system $(\mathcal{D}_0 \to \mathcal{D}_1)$ is complete in the sense that every filter in $|\mathcal{D}_0 \to \mathcal{D}_1|$ is fixed by a unique approximable mapping.

Proof: Let $f : \mathcal{D}_0 \to \mathcal{D}_1$ be an approximable mapping. By the very definition of $(\mathcal{D}_0 \to \mathcal{D}_1)$ it determines a filter by the definition:

$$\hat{f} = \{F \in (D_0 \to D_1) \mid f \in F\}.$$

Trivially $[X, Y] \in \hat{f}$ iff $f \in [X, Y]$ iff XfY; so this filter uniquely determines the relation f. What we have to show is that every filter in $|D_0 \to D_1|$ is of this form.

Suppose $\varphi \in |D_0 \to D_1|$ is any filter. A relation can be defined at once by

$$X\hat{\varphi}Y \quad \text{iff} \quad [X, Y] \in \varphi.$$

In view of the remarks we made just before stating this theorem, there is no problem in showing that $\hat{\varphi}$ is an approximable mapping. Since the neighbourhoods of the function space are in any case finite intersections of sets like $[X, Y]$, those $[X, Y] \in \varphi$ generate φ. This means that $\hat{\hat{\varphi}} = \varphi$. By definition $\hat{\hat{f}} = f$, so there is a one-one correspondence between mappings and filters. (This correspondence is obviously inclusion preserving, too.) □

We now know just about everything about $|D_0 \to D_1|$ as a domain: the elements correspond isomorphically to the approximable mappings; the finite elements are explained completely by 3.9; and we have seen how to calculate with neighbourhoods. The final step is to relate the function space to other domains by appropriate mappings. In doing this we shall freely construe elements of $|D_0 \to D_1|$ as approximable mappings in view of 3.10.

8

3.4.12 Theorem 3.11 — evaluation combinator

THEOREM 3.11. Given neighbourhood systems D_1 and D_2, there is a uniquely determined approximable mapping

$$\text{eval} : (D_1 \to D_2) \times D_1 \to D_2,$$

where for all $f : D_1 \to D_2$ and all $x \in |D_1|$ we have

(i) $\text{eval}(f, x) = f(x)$.

Proof: For $F \in (D_1 \to D_2)$ and $X \in D_1$ and $Y \in D_2$ define eval as a relation by:

$$F, X \text{ eval } Y \quad \text{iff} \quad X \mathrel{f} Y \text{ for all } f \in F.$$

Remember that neighbourhoods in the function space are sets of approximable mappings. It is easily checked that this definition makes eval approximable. We now calculate the function values by the formula of 2.2 (i):

$$\text{eval}(f,x) = \{Y \in D_2 \mid \exists F \in (D_1 \to D_2)\, \exists X \in x.\ f \in F \text{ and } F \cup X \text{ eval } Y\}$$

Because, again by 2.2 (i), we have

$$f(x) = \{Y \in D_2 \mid \exists X \in x.\ XfY\},$$

we can see from the definition of eval that $\text{eval}(f,x) \subseteq f(x)$. Suppose that $Y \in f(x)$. Then XfY holds for some $X \in x$. We can write $f \in [X,Y] \in (D_1 \to D_2)$ and it is clear that

$$[X,Y] \cup X \text{ eval } Y$$

holds by definition. Therefore, $Y \in \text{eval}(f,x)$, and so $f(x) \subseteq \text{eval}(f,x)$. □

This theorem is essential for our programme: it shows that in taking functions as objects the very basic operation of forming the function value is an approximable mapping. In other words we can treat the expression $f(x)$ not just as a function of x, as we have done from the start, but also as a function of f as well. The result also indicates that there are useful maps defined on domains that themselves are function spaces; we shall meet many more of these. The next theorem provides further examples.

3.4.13 Theorem 3.12 — currying

THEOREM 3.12. Given neighbourhood systems D_0, D_1, D_2 there is associated with every approximable mapping $g : D_0 \times D_1 \to D_2$ a uniquely determined approximable mapping

$$\text{curry}(g) : D_0 \to (D_1 \to D_2)$$

such that for $x \in |D_0|$ and $y \in |D_1|$

(i) $\text{curry}(g)(x)(y) = g(x, y)$.

Moreover we have these functional equations:

(ii) $\text{eval} \circ \langle \text{curry}(g) \circ p_0,\ p_1 \rangle = g$, and

(iii) $\text{curry}(\text{eval} \circ \langle h \circ p_0,\ p_1 \rangle) = h$,

where the $p_i : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_i$ are the projection mappings and $h : \mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2)$ is any approximable mapping. This provides an isomorphism between the domains $|\mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2|$ and $|\mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2)|$ and so we can regard

$$\text{curry} : (\mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_2) \to (\mathcal{D}_0 \to (\mathcal{D}_1 \to \mathcal{D}_2))$$

as itself being an approximable mapping.

Proof: Given g as indicated, we can define $\text{curry}(g)$ as a relation and as an approximable mapping by:

$$X\ \text{curry}(g)\ [Y, Z] \text{ iff } X \cup Y\ g\ Z \quad \text{(but see Ex. 3.21)}$$

for all $X \in \mathcal{D}_0$, $Y \in \mathcal{D}_1$, $Z \in \mathcal{D}_2$. This is sufficient because an approximable mapping is intersective in the right-hand neighbourhood, so we know from the above exactly what $X\ \text{curry}(g)\ \bigcap\{[Y_i, Z_i] \mid i < n\}$ means for all finite intersections. The remark after 3.9 is then helpful in checking that by this definition $\text{curry}(g)$ satisfies the monotonicity condition and so is indeed approximable. We now calculate:

$$\begin{aligned}
\text{curry}(g)(x)(y) &= \{Z \in \mathcal{D}_2 \mid \exists Y \in y.\ Y\ \text{curry}(g)\ (x)\ Z\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists Y \in y\ \exists X \in x.\ X\ \text{curry}(g)\ [Y, Z]\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists Y \in y\ \exists X \in x.\ X \cup Y\ g\ Z\} \\
&= \{Z \in \mathcal{D}_2 \mid \exists W \in \langle x, y \rangle.\ W\ g\ Z\} \\
&= g(\langle x, y \rangle) = g(x, y).
\end{aligned}$$

This proves (i). We also see, that if we take the left-hand side of (ii) and apply it to a pair $\langle x, y \rangle$, it reduces to $g(x, y)$ by virtue of (i). Thus, the two functions in (ii) are the same.

Turning to (iii), call the left-hand side k. Using (i) again, we find

$$\begin{aligned} k(x)(y) &= \mathrm{eval} \circ \langle h \circ p_0, p_1 \rangle (\langle x, y \rangle) \\ &= \mathrm{eval}(\langle h \circ p_0(\langle x, y \rangle), p_1(\langle x, y \rangle)\rangle) \\ &= \mathrm{eval}(\langle h(x), y \rangle) \\ &= h(x)(y). \end{aligned}$$

As this is true for all $y \in |\mathcal{D}_1|$, then $k(x) = h(x)$ follows. As this is true for all $x \in |\mathcal{D}_0|$, then $k = h$ follows, and (iii) is proved.

Taking (ii) and (iii) together, it is clear that the domains $|D_0 \times D_1 \to D_2|$ and $|D_0 \to (D_1 \to D_2)|$ are in a one-one correspondence.

$$\mathrm{curry}(g) \sqsubseteq \mathrm{curry}(g') \text{ iff } g \sqsubseteq g'.$$

Hence, curry is an isomorphism, and we can invoke 2.7 to conclude that it comes from an approximable mapping. □

We close this lecture with some order-theoretic properties of function spaces that characterize inclusion and upper bounds of functions in a "pointwise" manner.

3.4.14 Theorem 3.13 — pointwise order of maps

THEOREM 3.13. For approximable functions $f, g : D_0 \to D_1$ we have

(i) $f \sqsubseteq g$ iff $f(x) \sqsubseteq g(x)$ for all $x \in |D_0|$.

For subsets $F \subseteq |D_0 \to D_1|$ we have

(ii) F is bounded in $|D_0 \to D_1|$ iff $\{f(x) \mid f \in F\}$ is bounded in $|D_1|$ for each $x \in |D_0|$;

and in that case for all $x \in |D_0|$:

(iii) $(\bigsqcup F)(x) = \bigsqcup\{f(x) \mid f \in F\}$.

Proof. The implication in (i) from left to right follows because evaluation is monotone in the function as well as the argument. The converse implication is a consequence of 2.2(ii).

For the proof of (ii) and (iii) we see that by (i) if F is bounded, so is every set $\{f(x) \mid f \in F\}$. For the converse direction, it is clear that (iii) defines *some* pointwise mapping; we have only to prove that it is *approximable*. The calculation that $\sqcup F$ preserves directed unions (see 2.9 and 2.11) is probably the simplest way to reach the conclusion. □

3.4.15 Exercise 3.14 — tagged product of tokens

For the most part we can assume that there is at most a countable number of tokens; thus, without loss of generality the underlying sets Δ_i of given systems $\mathcal{D}_i$ could be assumed to be subsets of Σ^* where $\Sigma = \{0, 1\}$. (Any denumerable set would do.) Show that the product $\mathcal{D}_0 \times \mathcal{D}_1$ could be defined as the system over the set $0\Delta_0 \cup 1\Delta_1$ where

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{0X \cup 1Y \mid X \in \mathcal{D}_0 \text{ and } Y \in \mathcal{D}_1\}.$$

In other words, the assumption of the disjointness of Δ_0 and Δ_1 is unnecessary. Give, therefore, the revised definition of $\langle x, y\rangle$ for elements, and prove that for a single system $\mathcal{D}$, there exists an approximable mapping

$$\mathrm{diag} : \mathcal{D} \to \mathcal{D} \times \mathcal{D}$$

where $\mathrm{diag}(x) = \langle x, x\rangle$ for all $x \in |\mathcal{D}|$. Also extend the definition to a product of n-factors

$$\mathcal{D}_0 \times \mathcal{D}_1 \times \cdots \times \mathcal{D}_{n-1}$$

which will be a system over the set

$$\bigcup_{i<n} 1^i 0\Delta_i.$$

Note that for a 2-termed product we simplify $10\Delta_1$ to $1\Delta_1$.

3.4.16 Exercise 3.15 — product isomorphisms

Establish the usual isomorphisms:

(i) $\mathcal{D}_0 \times \mathcal{D}_1 \cong \mathcal{D}_1 \times \mathcal{D}_0$;

(ii) $\mathcal{D}_0 \times (\mathcal{D}_1 \times \mathcal{D}_2) \cong (\mathcal{D}_0 \times \mathcal{D}_1) \times \mathcal{D}_2 \cong \mathcal{D}_0 \times \mathcal{D}_1 \times \mathcal{D}_2$.

How does the product of no factors fit in? Prove also:

(iii) $\mathcal{D}_0 \cong \mathcal{D}_0'$ and $\mathcal{D}_1 \cong \mathcal{D}_1'$ imply $\mathcal{D}_0 \times \mathcal{D}_1 \cong \mathcal{D}_0' \times \mathcal{D}_1'$.

3.4.17 Exercise 3.16 — infinite sequences of elements

Let $\mathcal{D}$ be a given neighbourhood system over $\Delta \subseteq \Sigma^*$. Define

$$\Delta^\infty = \bigcup_{n=0}^{\infty} 1^n 0 \Delta,$$

so that Δ^∞ is split into infinitely many disjoint copies of Δ. Let $\mathcal{D}^\infty$ be the least family of subsets of Σ^* where

1. $\Delta^\infty \in \mathcal{D}^\infty$, and
2. whenever $X \in \mathcal{D}$ and $Y \in \mathcal{D}^\infty$, then $0X \cup 1Y \in \mathcal{D}^\infty$.

Show that $\mathcal{D}^\infty$ is a neighbourhood system over Δ^∞. Prove the isomorphism

$$\mathcal{D}^\infty \cong \mathcal{D} \times \mathcal{D}^\infty.$$

Show, moreover, that the elements of $|\mathcal{D}^\infty|$ are in a one-one correspondence with arbitrary infinite sequences $\langle x_n \rangle_{n=0}^\infty$ of elements $x_n \in |\mathcal{D}|$ by using combinations of neighbourhoods

$$0X_0 \cup 10X_1 \cup \cdots \cup 1^n 0X_n \cup \cdots,$$

where from some point on all the X_m are equal to Δ.

3.4.19 Exercise 3.18 — separated sum

Let $\mathcal{D}_0$ and $\mathcal{D}_1$ be neighbourhood systems over Δ_0 and Δ_1, where we again assume that these are subsets of Σ^*. We assume that in addition *no neighbourhood is empty*. Why is this possible without loss of generality?

Define the *sum system* by:

$$\mathcal{D}_0 + \mathcal{D}_1 = \{\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1\} \cup \{0X \mid X \in \mathcal{D}_0\} \cup \{1Y \mid Y \in \mathcal{D}_1\}.$$

Prove that this is a neighbourhood system over $\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1$. (Throwing in $\{\Lambda\}$ was not all that necessary, but note that $\mathcal{B} = \mathcal{B} + \mathcal{B}$, and this is an equality of sets not just an isomorphism of systems.)

Prove that in general there are mappings

$$in_i : \mathcal{D}_i \to \mathcal{D}_0 + \mathcal{D}_1 \quad \text{and} \quad out_i : \mathcal{D}_0 + \mathcal{D}_1 \to \mathcal{D}_i,$$

where $out_i \circ in_i = I_{\mathcal{D}_i}$. Where does the assumption $\emptyset \notin \mathcal{D}_i$ come in? How can these sums be generalized to n-terms? (Hint: As for products use sets $1^i 0\Delta_i$.) Draw some pictures.

3.4.20 Exercise 3.19 — induced maps on constructs

Suppose we are given systems and approximable mappings

$$f : \mathcal{D}_0 \to \mathcal{D}_0' \quad \text{and} \quad g : \mathcal{D}_1 \to \mathcal{D}_1'.$$

Prove there are approximable mappings

$$f \times g : \mathcal{D}_0 \times \mathcal{D}_1 \to \mathcal{D}_0' \times \mathcal{D}_1' \quad \text{and} \quad f + g : \mathcal{D}_0 + \mathcal{D}_1 \to \mathcal{D}_0' + \mathcal{D}_1'$$

such that

(i) $(f \times g)(x, y) = \langle f(x), g(y) \rangle$ for all $x \in |\mathcal{D}_0|$ and $y \in |\mathcal{D}_1|$, and rewrite this as:

(ii) $f \times g = \langle f \circ p_0, g \circ p_1 \rangle$.

In addition prove that

(iii) $out_0 \circ (f + g) \circ in_0 = f$, and

(iv) $out_1 \circ (f + g) \circ in_1 = g$.

Do equations (iii) and (iv) uniquely determine $f + g$?

3.4.22 Exercise 3.21 — identity of step neighbourhoods

In the proofs of 3.12 in the definition of curry (g) it is rather cavalierly assumed that the neighbourhood $[Y, Z]$ uniquely determines Y and Z. Show that this is true if $Z \neq \Delta_2$. (Hint: Find explicitly the least of $f \in [Y, Z]$.) Show that if $Z = \Delta_2$ the biconditional stated at the start of the proof is still valid even though Y is not uniquely determined. (Hint: Remember that $\Delta_1\ g\ \Delta_2$ must hold.) For arbitrary pairs of neighbourhoods of $(D_1 \to D_2)$ is there a simple criterion for identity?

lt.lean

end DomainTheory.ContinuousLattice
```

0

3.4.23 Exercise 3.22 — composition combinator

Prove that there is an approximable mapping

$$\text{comp} : (D_1 \to D_2) \times (D_0 \to D_1) \to (D_0 \to D_2)$$

where for all $g : D_1 \to D_2$ and $f : D_0 \to D_1$ we have

$$\text{comp}(g, f) = g \circ f.$$

Show this directly by writing down the neighbourhood relation and by building the mapping up from eval and curry (on suitable domains) using $\circ$ and $\langle , \rangle$. (Hint: Fill in maps in the following sequence of domains:

1. $(D_0 \to D_1) \times D_0 \to D_1$
2. $(D_1 \to D_2) \times ((D_0 \to D_1) \times D_0) \to (D_1 \to D_2) \times D_1$
3. $((D_1 \to D_2) \times (D_0 \to D_1)) \times D_0 \to (D_1 \to D_2) \times D_1$
4. $((D_1 \to D_2) \times (D_0 \to D_1)) \times D_0 \to D_2$
5. $(D_1 \to D_2) \times (D_0 \to D_1) \to (D_0 \to D_2)$.

The maps are of course not uniquely determined, but the shifting of brackets ought to suggest the right choice.)

3.4.28 Exercise 3.27 — function space via closure

(For set theorists.) Give another proof that the family of approximable mappings $f : D_0 \to D_1$ is isomorphic to a domain by employing the general argument of Exercise 2.22. How does this compare with the proof method of 3.9 and 3.10? Can the general remarks also be employed to show that

$$\text{eval} : (D_1 \to D_2) \times D_1 \to D_2$$

is approximable without bringing in the neighbourhoods in such an explicit way? (Hint: Use 3.5 and the idea of Exercise 2.12.)

3.4.29 Exercise 3.28 — minimal step function

In the function space $(D_0 \to D_1)$ let

$$\bigcap\{[X_i, Y_i] \mid i < n\}$$

be a (non-empty) neighbourhood. In 3.9 the minimal element of this neighbourhood is characterized as a relation f_0. Show that as an elementwise mapping it can be defined by the formula

$$f_0(x) = \bigsqcup\{\uparrow Y_i \mid x \in [X_i]\},$$

for $x \in |D_0|$. Try to draw a picture of $|D_0|$ with neighbourhoods $[X_i]$ and the corresponding values of the function f_0.

LECTURE IV FIXED POINTS AND RECURSION

Having at this point a large supply of examples of domains (and further constructs of new domains), we now have to consider some other ways of defining functions — other than by explicit compositions of the very basic functions already mentioned. One of the most fruitful techniques is an infinitely iterated composition that is at the back of the idea of recursion. We will use the process over and over again in these lectures, not only to define new functions but also to define new domains. The heart of the matter lies in the so-called "Fixed-point Theorem":

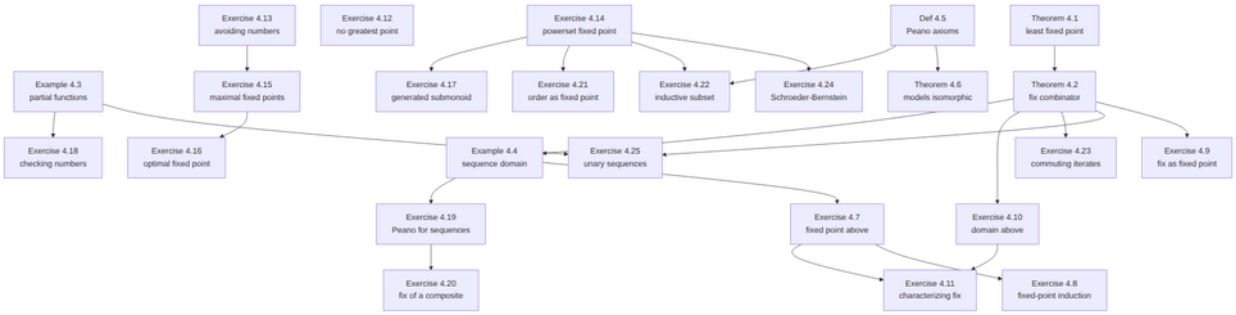

Figure 31: Fixed points and recursion.

3.5.1 Introduction

LECTURE IV FIXED POINTS AND RECURSION

Having at this point a large supply of examples of domains (and further constructs of new domains), we now have to consider some other ways of defining functions — other than by explicit compositions of the very basic functions already mentioned. One of the most fruitful techniques is an infinitely iterated composition that is at the back of the idea of recursion. We will use the process over and over again in these lectures, not only to define new functions but also to define new domains. The heart of the matter lies in the so-called "Fixed-point Theorem":

3.5.2 Theorem 4.1 — least fixed point

THEOREM 4.1. For any approximable mapping $f : D \to D$ on any domain, there exists a least element $x \in |D|$ where

$$f(x) = x.$$

Proof: Let f^n for $n \in \mathbf{N}$ stand for the n-fold composition of f with itself. That is,

$$f^0 = I_D, \text{ and}$$

$$f^{n+1} = f \circ f^n.$$

Define

$$x = \{X \in D \mid \Delta \; f^n \; X, \text{ for some } n \in \mathbf{N}\}.$$

We see $X \in x$ iff there is a finite sequence $\Delta = X_0, X_1, \ldots, X_n = X$ where $X_i \; f \; X_{i+1}$ holds for all $i < n$. Now since $\Delta \; f \; \Delta$ automatically holds, a sequence for an $X \in x$ can always be extended to a longer sequence just by adding more Δ's on the front.

We want to prove $x \in |D|$. Clearly $\Delta \in x$; and if $X \subseteq Y$ and $X \in x$, then $Y \in x$. All that remains to be shown is the closure of x under intersection. Note that if

$$U \; f \; V \quad \text{and} \quad U' \; f \; V'$$

hold and U, U' are consistent in D, then V and V' are consistent and
$(U \cap U') \; f \; (V \cap V')$
must hold. Generalizing this to sequences, if

$$\Delta = X_0 \; f \; X_1 \; f \; \cdots \; f \; X_n = X, \text{ and}$$

$$\Delta = Y_0 \; f \; Y_1 \; f \; \cdots \; f \; Y_n = Y$$

both hold (and note we have arranged the lengths of the two sequences to be equal), then each pair X_i, Y_i is consistent and we have

$$\Delta = (X_0 \cap Y_0) \; f \; (X_1 \cap Y_1) \; f \; \cdots \; f \; (X_n \cap Y_n) = X \cap Y.$$

This establishes the desired closure.

We also note that if $X \in x$ and $X \; f \; Y$ then $Y \in x$. Therefore, $f(x) \subseteq x$ and indeed by its very construction x is the *least* element of $|D|$ with this property. (Why?) But f is monotone, so $f(f(x)) \subseteq f(x)$; hence, $x = f(x)$. By what we have already said it must be the least such element. □

Because the element we have shown to exist in 4.1 is a least element, it is unique. That is, we have associated with each $f : D \to D$ a special element $x_f \in |D|$ determined by the choice of f. A function has therefore been defined mapping the set $|D \to D|$ into $|D|$. The next result shows that this function, or operator on functions, is in fact approximable.

3.5.3 Theorem 4.2 — fix combinator

THEOREM 4.2. For any domain D, there is an approximable mapping

$$\mathrm{fix} : (D \to D) \to D$$

such that if $f : D \to D$ is any approximable mapping, then

(i) $\mathrm{fix}(f) = f(\mathrm{fix}(f))$.

Furthermore, if $x \in |D|$, then

(ii) $f(x) \subseteq x$ implies $\mathrm{fix}(f) \subseteq x$.

And this last property implies that fix is unique. Explicitly we can characterize fix by the equation:

(iii)

$$\mathrm{fix}(f) = \bigcup_{n=0}^{\infty} f^n(\bot),$$

for all $f : D \to D$.

Proof: Formula (iii) can be put in a more elementary form:

$$\mathrm{fix}(f) = \{X \mid \Delta f^n X, \text{ for some } n \in \mathbf{N}\}.$$

To show an elementwise mapping approximable we can use the formula of Exercise 2.9, applied to the above as the definition of fix:

$$(*) \quad \mathrm{fix}(f) = \bigcup\{\mathrm{fix}(\uparrow F) \mid f \in [F]\},$$

where F ranges over the neighbourhoods of $(D \to D)$, and where $\uparrow F$ can be considered to be the least element of F as calculated in 3.9.

Now from the definition of fix, it is clear that whenever $f \subseteq g$, then $\mathrm{fix}(f) \subseteq \mathrm{fix}(g)$, because $f^n \subseteq g^n$. (That is, fix is obviously monotone.) Next, if $f \in F$, then $\uparrow F$ is a (finite) approximation to f; so $\uparrow F \subseteq f$ and $\mathrm{fix}(\uparrow F) \subseteq \mathrm{fix}(f)$. This means that half of equation (*) already holds by monotonicity. All that is left is to prove the other half.

So suppose $X \in \mathrm{fix}(f)$. Then, as we have already remarked, there is a finite sequence of neighbourhoods where

$$\Delta = X_0 \; f \; X_1 \; \ldots \; X_{n-1} \; f \; X_n = X.$$

Let the function-space neighbourhood be defined as

$$F = \bigcap\{[X_i, X_{i+1}] \mid i < n\},$$

and note that since $f \in [F]$ we have at once consistency. But, by 3.9, $\uparrow F \in [F]$, so the *same* sequence of X_i is sufficient to show that

$$X \in \mathrm{fix}(\uparrow F).$$

In other words, if X belongs to the left-hand side of *(), it also belongs to the right-hand side. This completes the proof of ()*.

Formula (i) is just a restatement of what we proved in 4.1. And (ii) follows easily, because $f(x) \subseteq x$ implies that $\Delta \in x$ and whenever $X \in x$ and $X \; f \; Y$, then $Y \in x$. Thus, by induction, if $\Delta f^n X$, then $X \in x$. So $\mathrm{fix}(f) \subseteq x$.

Finally, if $\mathrm{fax} : (D \to D) \to D$ were any other operator satisfying (i) and (ii), we would prove at once that

$$\mathrm{fix}(f) \subseteq \mathrm{fax}(f) \quad \text{and}$$

$$\mathrm{fax}(f) \subseteq \mathrm{fix}(f).$$

That is to say, the two operators are identical. □

The reader may have noticed that we used recursion in the proof of 4.1 (we had to define f^n for all $n \in \mathbf{N}$). But 4.1 and 4.2 can be used to justify definitions by recursion on a large number of domains —

definitions where the process of iteration is far from being as straightforward. In discussing this point, let us start with some basic examples.

3.5.4 Example 4.3 — partial functions on integers

EXAMPLE 4.3. The infinite generalization of our original example 1.2 is the system

$$N = \{\{n\} \mid n \in \mathbf{N}\} \cup \{\mathbf{N}\}.$$

The total elements are clearly in a one-one correspondence with the integers in $\mathbf{N}$. We can apply the construction of Exercise 3.16 to obtain a domain

$$F = N^{\infty}.$$

So we already know quite a bit about this domain — but it has a much more familiar presentation.

Let Φ be the set of all *finite partial functions* $\varphi \subseteq \mathbf{N} \times \mathbf{N}$ (that is, finite sets of ordered pairs of integers where, if $(n, m) \in \varphi$ and $(n, m') \in \varphi$, then $m = m'$). Define

$$\uparrow \varphi = \{\psi \in \Phi \mid \varphi \subseteq \psi\}.$$

Consider the neighbourhood system

$$F' = \{\uparrow \varphi \mid \varphi \in \Phi\}.$$

It is an easy exercise to show that F and F' are isomorphic and that the elements of these domains correspond exactly to the (possibly infinite) *partial functions* $\pi \subseteq \mathbf{N} \times \mathbf{N}$. Moreover, the *total* elements just correspond to the *total* functions $\tau : \mathbf{N} \to \mathbf{N}$ ("function" in the ordinary, set-theoretical sense of the word).

Another easy exercise is to show that the domains

$$F \text{ and } (\mathbf{N} \to \mathbf{N})$$

by our definitions are *NOT* isomorphic; though the two domains are closely related. We can define a mapping

$$\text{val} : F \times N \to N$$

by the relationship

$$\uparrow \phi \cup \{n\} \text{ val } \{m\} \quad \text{iff} \quad (n, m) \in \phi.$$

(Of course val has to relate other neighbourhoods such as:

$$\uparrow \phi \cup N \text{ val } N,$$

but these are all.) It is then simple to prove that if $\pi \in |F|$ is regarded as a partial function $\pi : N \to N$ and if for $n \in N$ we define $\hat{n} \in |N|$ by

$$\hat{n} = \{\{n\}, N\},$$

then we have

$$\text{val}(\pi, \hat{n}) = \widehat{\pi(n)}, \text{ if } \pi \text{ is defined at } n;$$

$$= \{N\}, \text{ otherwise.}$$

(Remember that $\{N\} \in |N|$ is the "undefined" element.) This means that

$$\text{curry}(\text{val}) : F \to (N \to N)$$

is a one-one function on elements. (The rather slight trouble with $(N \to N)$ is that it has *more* elements than F.)

So much for the construction of F, we now wish to consider mappings

$$f : F \to F$$

and their uses. Consider the possibility

$$f(\pi)(n) = 0, \qquad \text{if } n = 0;$$

$$= \pi(n-1) + n - 1, \text{ if } n > 0.$$

If π were a total function, then $f(\pi)$ would be total. But if π is partial, and if it is, say, undefined at k, then $f(\pi)$ becomes undefined at $k+1$. Note that $f(\pi)$ is always defined at 0. Note, too, that f is an approximable mapping because it is completely determined by what it does to finite (partial) functions. Indeed,

$$f(\pi) = \bigcup\{f(\phi) \mid \phi \subseteq \pi\},$$

where ϕ ranges over Φ.

Well, we have proved that every approximable map of a domain into itself has a (*least*) fixed point. What is the least fixed point of this f? Suppose $\sigma = f(\sigma)$. Then $\sigma(0) = 0$, and

$$\sigma(n+1) = f(\sigma)(n+1)$$

$$= \sigma(n) + n.$$

By induction, then

$$\sigma(n) = \sum_{i<n} i$$

and σ is a total function. (Therefore, f has a *unique* fixed point.)

Actually, we can make the procedure more systematic by defining as fixed points elements of $(N \to N)$ rather than F. In the first place we have $\hat{0} \in |N|$, and from now on we will not distinguish between n and $\hat{n}$. Next we have two mappings:

$$\text{succ}, \text{pred} : N \to N$$

where, as approximable mappings we have

$$X \text{ succ } Y \text{ iff } \exists n \in N.\ n \in X \text{ and } n+1 \in Y,$$

$$X \text{ pred } Y \text{ iff } \exists n \in N.\ n+1 \in X \text{ and } n \in Y,$$

for all $X, Y \in N$. This is *correct*, but what we mean in more understandable terms is:

$$\text{succ}(n) = n + 1;$$

$$\text{pred}(n) = n - 1, \text{ if } n > 0;$$

$$= \perp, \text{ if } n = 0.$$

Here, n has been identified with $\hat{n} \in |N|$ and $\perp = \{N\} \in |N|$. Moreover, we have a mapping

$$\text{zero} : N \to T$$

which is such that

$$\text{zero}(n) = \text{true, if } n = 0;$$

$$= \text{false, if } n > 0.$$

The *structured domain*

$$\langle N, 0, \text{succ}, \text{pred}, \text{zero} \rangle$$

can be called "THE domain of integers" for our present theory. We shall meet many other structured domains in the sequel.

Now the iterated summation function σ can be completely characterized — as a map $\sigma : N \to N$ rather than as an element $\sigma \in |F|$ — by the following equation:

$$\sigma(n) = \text{cond}(\text{zero}(n),\ 0,\ \sigma(\text{pred}(n)) + \text{pred}(n)).$$

The only problem is that we have not defined $+ : N \times N \to N$. (A direct definition is left to the reader; general remarks are given later.) But $+$ could be any function of two variables in order to make the point about the form of the definition of σ. Remember

$$\text{cond} : T \times N \times N \to N,$$

as defined in Exercise 3.26. We do not put cond in as part of the structure of N because (as should be clear from 3.26) it is part of the structure of T.

The above equation for σ is properly called a *functional equation*; it will be written as a fixed-point equation in Lecture V when we have the notation for the λ-calculus. □

3.5.5 Example 4.4 — sequence domain

EXAMPLE 4.4. The domain C of finite or infinite binary sequences mentioned in Exercise 2.21 may be regarded as a generalization of N. This can be made plain by saying how we wish to regard C as a structured domain. To do this we should recall what C is as a neighbourhood system. In the first place

$$B = \{\sigma\Sigma^* \mid \sigma \in \Sigma^*\}$$

where $\Sigma = \{0, 1\}$. To form the system C we have

$$C = B \cup \{\{\sigma\} \mid \sigma \in \Sigma^*\}.$$

The total elements of B correspond to *infinite binary sequences*; while the total elements of C to *finite or infinite sequences*. To simplify notation let us write for $\sigma \in \Sigma^*$

$$\sigma = \uparrow \{\sigma\} \quad \text{(a total element);}$$

$$\sigma \perp = \uparrow \sigma\Sigma^* \quad \text{(a partial element).}$$

In other words we identify σ with the corresponding total element in $|C|$.

We wish now to think of C as a structured domain seen as a kind of generalization of N. The empty sequence Λ will play the rôle of $0 \in |N|$; the map succ has two different analogues for C, however. Just as for B we define for $x \in |C|$ and $\sigma \in \Sigma^*$:

$$\sigma x = \{Y \mid \sigma X \subseteq Y \text{ some } X \in x\},$$

where of course now X and Y range over C. It should be checked that $\sigma\tau$ has the right meaning whether we think of $\tau \in \Sigma^*$ or $\tau \in |C|$. The two "successor" mappings we are looking for are

$$x \mapsto 0x \quad \text{and} \quad x \mapsto 1x.$$

All the maps $x \mapsto \sigma x$ can be obtained as compositions of these iterated as many times as needed.

Here are two questions which we now should ask:

What plays the rôle of pred?

The mapping will be called **tail**, and it is characterized by:

$$\mathrm{tail}(0x) = x,$$

$$\mathrm{tail}(1x) = x, \text{ and}$$

$$\mathrm{tail}(\Lambda) = \perp .$$

It is left to the reader to show that **tail** exists as an approximable mapping.

What plays the rôle of zero?

The answer is not unique, because in C there are several distinctions that have to be made; in fact we will define three maps:

$$\mathrm{empty}, \mathrm{zero}, \mathrm{one} : C \to T$$

where the three maps take on truth-values to distinguish various kinds of elements in $|C|$ as follows:

$$\begin{aligned}
\mathrm{empty}\,(\Lambda) &= \mathrm{true},\\
\mathrm{empty}\,(0x) &= \mathrm{false},\\
\mathrm{empty}\,(1x) &= \mathrm{false},\\
\mathrm{zero}\,(\Lambda) &= \mathrm{false}\\
\mathrm{zero}\,(0x) &= \mathrm{true}\\
\mathrm{zero}\,(1x) &= \mathrm{false}\\
\mathrm{one}\,(\Lambda) &= \mathrm{false}\\
\mathrm{one}\,(0x) &= \mathrm{false}\\
\mathrm{one}\,(1x) &= \mathrm{true}.
\end{aligned}$$

Again, it is an exercise to show these are approximable. The structured domain is therefore

$$\langle C, \Lambda, 0, 1, \mathrm{tail}, \mathrm{empty}, \mathrm{zero}, \mathrm{one}\rangle.$$

Note that we have changed the meaning of some of the symbols in passing from N to C. Note too that there is a confusion between 0 as an element and 0 as the map $x \mapsto 0x$. There are just too few symbols! In any case this is only an example and not a philosophy of life, so the reader can be expected not to suffer too much.

An example of a definition of an *element* of $|C|$ by a fixed-point equation is:

$$a = 0\,1\,a.$$

This equation has one and only one solution in $|C|$, the infinite sequence that alternates 0's and 1's. Note that a is also characterized by:

$$a = 0101a.$$

Another element is

$$b = 010\,b,$$

which is quite different from a.
An example of a *map* in $|C \to C|$ has the characterization

$$\begin{aligned} d(\Lambda) &= \Lambda \\ d(0x) &= 00d(x), \quad \text{and} \\ d(1x) &= 11d(x). \end{aligned}$$

We can write:

$$\begin{aligned} d(x) = \mathrm{cond}(&\mathrm{empty}(x),\ \Lambda, \\ &\mathrm{cond}(\mathrm{zero}(x),\ 00d(\mathrm{tail}(x)),\ 11d(\mathrm{tail}(x)))). \end{aligned}$$

As we shall see in due course, this can be regarded as a fixed-point definition of d.
An example of a map in $|C \times C \to C|$ was suggested in 2.21. We can write:

$$\begin{aligned} xy = \mathrm{cond}(&\mathrm{empty}(x),\ y, \\ &\mathrm{cond}(\mathrm{zero}(x),\ 0(\mathrm{tail}(x)\,y),\ 1(\mathrm{tail}(x)\,y))). \end{aligned}$$

It should be checked that this equation exactly characterizes the intended mapping. □
