EXERCISE 7.20. Show that there is a combinator

$$\text{union} : \mathbb{P}(\mathbb{P}D) \to \mathbb{P}D$$

where for suitable neighbourhoods

$$\bigcup_{i<n} \downarrow \Big(\bigcup_{j<m_i} \downarrow X_{ij} \Big) \quad \text{union} \quad \bigcup_{k<q} \downarrow Y_k \quad \text{iff} \quad \forall i < n \forall j < m_i \exists k < q.\, X_{ij} \subseteq Y_k\,.$$

Is union computable if D is effectively given? What is

$$\text{union}(\{\{x\},\{y,z\}\}) = ??$$

Are $\mathbb{P}(\mathbb{P}D)$ and $\mathbb{P}D$ generally isomorphic??

3.8.23 Exercise 7.21 — distributing the power domain

EXERCISE 7.21. Is there a non-trivial combinator of type

$$\mathbb{P}(D \to E) \to (\mathbb{P}D \to \mathbb{P}E)\,?$$

Are there in general any isomorphisms between the systems

$$(D \to \mathbb{P}E),\ \mathbb{P}(D \times E),\ \mathbb{P}D \times \mathbb{P}E\ ??$$

Is there a non-trivial combinator of type

$$\mathbb{P}(D \times E) \times \mathbb{P}(E \times F) \to \mathbb{P}(D \times F)\ ???$$

Is there any connection between

$$\mathbb{P}\mathbf{N} \text{ and } P\mathbf{N}\ ????$$

3.8.24 Exercise 7.22 — domain of formal languages

(For algebraists.) Let $\Sigma = \{0, 1\}^*$ be the free semigroup. A new domain is constructed by defining a family of sets by the least fixed point theorem as follows:

$$S = \{\Sigma\} \cup \{\{\sigma\} \mid \sigma \in \Sigma\} \cup \{XY \mid X, Y \in S\} \cup \{X \cap Y \mid X, Y \in S \text{ and } X \cap Y \neq \emptyset\}.$$

Here we write: $XY = \{\sigma\tau \mid \sigma \in X \text{ and } \tau \in Y\}$.

Prove that S is an effectively given, positive neighbourhood system. (Hint: The sets in S are each "regular events" in the terminology of automata theory, and we have a decision method for the set algebra of regular events.)

Define multiplication on $|S|$ by

$$xy = \{Z \in S \mid \exists X \in x\ \exists Y \in y.\ XY \subseteq Z\},$$

and show $|S|$ becomes a semigroup with Σ embedded into $|S|$ by the homomorphism $\sigma \mapsto \{X \in S \mid \sigma \in X\}$.

Investigate some *infinite words* in S, say those defined by least fixed points such as: $\vec{\sigma} = \sigma\,\vec{\sigma}$ and $\vec{\sigma} = \vec{\sigma}\,\sigma$. Are these equations true:

$$\vec{\sigma}\,\vec{\sigma} = \vec{\sigma}, \quad \vec{\sigma}\,\vec{\sigma}\,\vec{\sigma} = \vec{\sigma}, \quad \vec{\sigma}\,\vec{1}\,\vec{\sigma}\,\vec{1} = \vec{\sigma}\,\vec{1},$$

and $\vec{01}\,\vec{01}\,\vec{01}\,\vec{01} = \vec{01}\,\vec{01}$?

3.8.25 Exercise 7.23 — graph and fun computable

Complete the discussion of $P\mathbf{N}$ of Example 7.8. Show that the combinators fun and graph of Exercise 5.14 are computable. Also do the same for

$$\lambda x, y.\, x \cap y, \quad \lambda x, y.\, x \cup y, \quad \text{and } \lambda x, y.\, x + y,$$

where for $x, y \in P\mathbf{N}$ we define

$$x + y = \{n + m \mid n \in x \text{ and } m \in y\}.$$

What are the computable elements of $P\mathbf{N}$?

3.8.26 Exercise 7.24 — LUCID history domain

(Suggested by the LUCID language of Ashcroft and Wadge: SIAM Jour. Comp. vol. 5 (1976).)

Define a set Γ by

$$\Gamma = \bigcup_{i=0}^{\infty} (\{i\} \times \Gamma) \cup \{\star\}.$$

Define a system

$$L = \{\Gamma\} \cup \{\{i\} \times X \mid i \in \mathbf{N} \text{ and } X \in L\}.$$

Show that L is effectively given. Show that the elements of $|L|$ can be identified with the finite and infinite sequences of natural numbers. What is the connection between B and L?

Show that the combinators of LUCID can be construed as computable mappings of type

$$(L \to T) \to (L \to T)$$

or of type

$$(L \to T) \times (L \to T) \to (L \to T).$$

Conclude that programs in LUCID define computable maps.

3.9 Retracts of the universal domain

Dependency diagram. Each box is one item. The arrowhead is on the item that imports. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it is not shown. Blue is a definition, green a proposition, amber an example, red a theorem, and indigo an exercise.

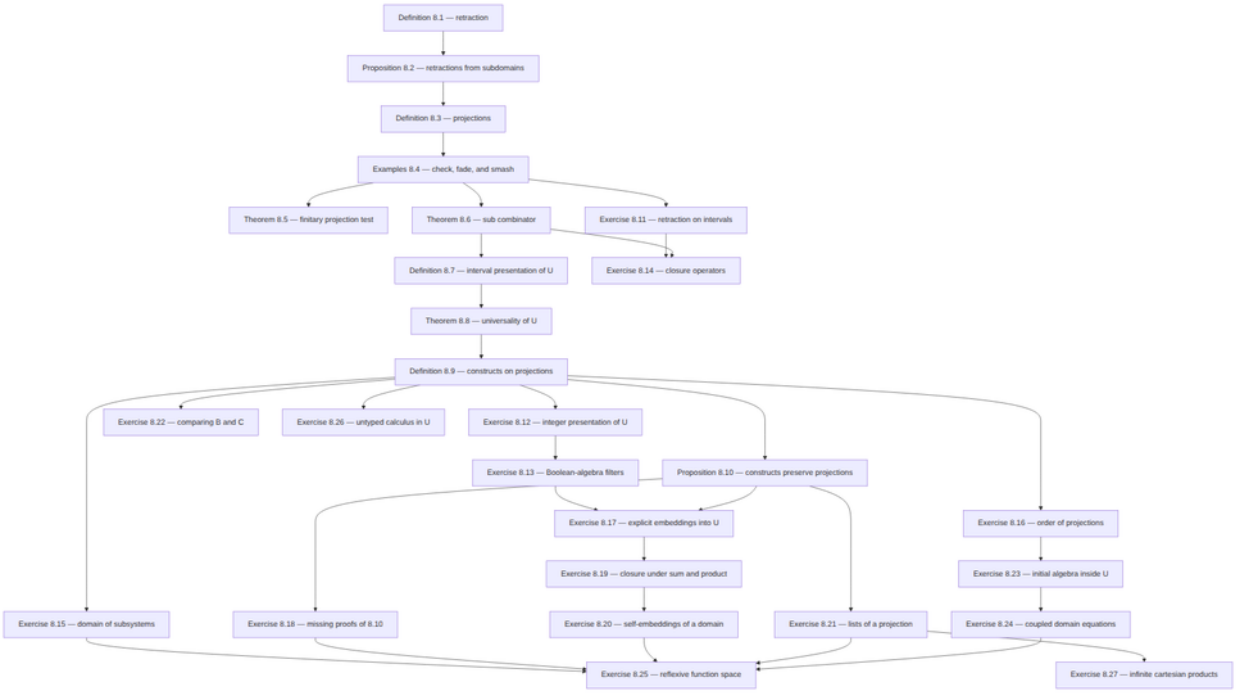

Figure 46: Retracts of the universal domain.

3.9.1 Introduction

LECTURE VIII RETRACTS OF THE UNIVERSAL DOMAIN

In order to be able to have a fully flexible method of solving domain equations and to be able to see why the domains obtained are effectively given, we shall embed all the desired domains in one "largest" domain. This universal domain will be easily shown to be effectively given, and the mappings needed to extract the other domains will be found to be computable. In order to be able to carry out this programme, we investigate first how certain subdomains correspond to mappings — the so-called *retracts*. An advantage of this analysis is that all the necessary definitions can be written out in λ-calculus notation, thus demonstrating the power of our mathematical programming language.

3.9.2 Definition 8.1 — retraction

DEFINITION 8.1. A retraction of a given domain E is an approximable mapping $a : E \to E$ such that $a \circ a = a$. □

3.9.3 Proposition 8.2 — retractions from subdomains

PROPOSITION 8.2. If $D \triangleleft E$ and if $a : E \to E$ is defined by

$$X\ a\ Z \quad \text{iff} \quad \exists Y \in D.\ X \subseteq Y \subseteq Z$$

for all $X, Z \in E$, then a is a retraction and $|D|$ is isomorphic to the fixed-point set of a, the set $\{y \in |E| \mid a(y) = y\}$, under inclusion.

Proof: That a is an approximable mapping is a direct consequence of Definition 6.10. Indeed, in the notation of Proposition 6.12, we have

$$a = i \circ j,$$

and this is another proof that a is approximable. This remark is also convenient, since we know from 6.10

$$j \circ i = I_D.$$

Therefore, we find:

$$a \circ a = i \circ j \circ i \circ j = i \circ j = a;$$

and so a is a retraction.

We can also employ i and j to give the isomorphism on $|D|$. If $x \in |D|$, then $i(x) \in |E|$ and we calculate:

$$a(i(x)) = i \circ j \circ i(x) = i(x).$$

Thus, $i(x)$ belongs to the fixed-point set of a. In the other direction, if $a(y) = y$, then $i(j(y)) = y$. But $j(y) \in |D|$, so i maps $|D|$ one-one and onto the fixed-point set of a. As i and j are monotone, the map is an isomorphism with respect to $\sqsubseteq$. $\square$

Not every retraction comes from a relationship like $D \triangleleft E$; in fact, we can see from the definition of a above that $a \sqsubseteq 1_E$. But, as is indicated in Exercise 8.11, even this condition is not sufficient to characterize the kind of retractions provided by 8.2. The characterization is as follows.

3.9.4 Definition 8.3 — projections

DEFINITION 8.3. A retraction $a : E \to E$ is called a *projection* provided

$$a \sqsubseteq 1_E;$$

it is *finitary* iff its fixed-point set is isomorphic to a domain. □

3.9.5 Examples 8.4 — check, fade, and smash

EXAMPLES 8.4. If a system D over Δ is not trivial, then the two element system $O = \{\{0\}, \{0, 1\}\}$ comes from a retraction on D. Specifically, define a combinator

$$\mathrm{check} : D \to O$$

by the relation

$$X \text{ check } Y \quad \text{iff either } Y = \{0, 1\} \text{ or } X \neq \Delta.$$

We see $\mathrm{check}(x) = \bot_O$ iff $x = \bot_D$. We leave to the reader the definition of a combinator:

$$\mathrm{fade} : O \times D \to D,$$

where we have for $t \in |O|$ and $x \in |D|$:

$$\begin{aligned} \mathrm{fade}(t, x) &= \bot_D, \text{ if } t = \bot_O; \\ &= x, \text{ if not.} \end{aligned}$$

Now, take any $u \in |D|$ with $u \neq \bot$, and define

$$a(x) = \mathrm{fade}(\mathrm{check}(x), u).$$

Then a is a retraction (not a projection in general) and the range of a is isomorphic to O.

Another way of using these combinators is to find $(D \to_\bot E)$ as a retraction of $(D \to E)$. Specifically, define a combinator

$$\mathrm{strict} : (D \to E) \to (D \to E)$$

by the equation

$$\mathrm{strict}(f) = \lambda x.\ \mathrm{fade}(\mathrm{check}(x), f(x)),$$

where this time

$$\mathrm{fade} : O \times E \to E\ .$$

The range of strict consists exactly of the strict functions and this time strict is a projection whose range is indeed a domain.

Similarly, we can find a projection on $D \times E$ with a range isomorphic to $D \otimes E$ by the combinator such that:

$$\mathrm{smash}(x, y) = \mathrm{fade}(\mathrm{check}(x), \mathrm{fade}(\mathrm{check}(y), \langle x, y \rangle)),$$

for $x \in |D|$ and $y \in |E|$. □

3.9.6 Theorem 8.5 — finitary projection test

THEOREM 8.5. For an approximable mapping $a : E \to E$ the following are equivalent:

(i) a is a finitary projection;

(ii) $a(x) = \{Y \in E \mid \exists X \in x.\, X \subseteq Y \wedge X\ a\ X\}$, for all $x \in |E|$.

Proof: Suppose a satisfies (ii) first. Inasmuch as $X \in x$ and $X \subseteq Y$ always imply $Y \in x$, for all $x \in |E|$, we see $a(x) \subseteq x$ must always hold. Moreover, it is obvious that $X \in x$ and $X\ a\ X$ always imply $X \in a(x)$; therefore, $a(x) \subseteq a(a(x))$ for all $x \in |E|$. This shows that a
is indeed a projection.

Let $D = \{X \in E \mid X\ a\ X\}$, then it is easy to check that $D \mathrel{\triangleleft} E$ and that a is determined from D exactly as in 8.2; thus, the fixed-point set of a is isomorphic to a domain, by what we have already proved. So we have shown (ii) implies (i).

In the converse direction, assume that a is a finitary projection. And let the system D be isomorphic to the fixed-point set of a. We have the situation of Theorem 6.15. There is a projection pair,

$$i : D \to E \quad \text{and} \quad j : E \to D,$$

where the connection with a gives:

$$j \circ i = I_D \quad \text{and} \quad i \circ j = a \subseteq I_E.$$

By 6.15, $D \cong D' \mathrel{\triangleleft} E$, and we want to identify D' in terms of a as follows:

$$D' = \{X \in E \mid X\ a\ X\}.$$

Now from a reading of the proof of 6.15 the neighbourhoods of D' are just those corresponding to the finite elements of D. But any such element is a fixed point of a. We have

$$X \in D' \quad \text{implies} \quad a(\uparrow X) = \uparrow X \quad \text{implies} \quad X\ a\ X.$$

Conversely, if $X\ a\ X$ holds, then $\uparrow X \subseteq a(\uparrow X)$. But a is a projection, so $\uparrow X$ is a fixed point. But $i(j(\uparrow X)) = \uparrow X$ means $j(\uparrow X)$ is a finite element of $|D|$. So $X \in D'$, and we have D' identified as desired.

Finally, if we calculate $a = i \circ j$ by the formulae of 6.12 (with D' for D, of course), we obtain our formula (ii). □

The criterion for being a finitary projection just obtained provides us with a very interesting new combinator.

3.9.7 Theorem 8.6 — sub combinator

THEOREM 8.6. For any domain E define

$$\mathrm{sub} : (E \to E) \to (E \to E)$$

by the formula

$$X \ \mathrm{sub}\ (f)\ Z \quad \text{iff} \quad \exists Y \in E.\quad X \subseteq Y \ \ f\ Y \subseteq Z,$$

for all $X, Z \in E$ and all $f : E \to E$. Then the range of sub consists exactly of the finitary projections on E, and moreover sub itself is a finitary projection on $(E \to E)$. If E is effectively given, then sub is computable.

Proof: It is trivial to check that $\mathrm{sub}(f)$ is always approximable. Also, it is obvious from the definition that the correspondence

$$f \mapsto \mathrm{sub}(f)$$

preserves directed unions of f's. Thus, sub is itself approximable. We note that

$$X \subseteq Y \ \ f\ Y \subseteq Z \text{ always implies } X\ f\ Z;$$

hence, $\mathrm{sub}(f) \subseteq f$ holds. Also

$$Y\ f\ Y \text{ always implies } Y\ \mathrm{sub}(f)\ Y,$$

hence, $\mathrm{sub}(f) \subseteq \mathrm{sub}(\mathrm{sub}(f))$ holds. This shows sub to be a projection on $(E \to E)$. The effectiveness of the definition makes it also clear that sub is computable when E has a computable presentation.

Since, sub is a projection, its range is the same as its fixed-point set. If

$$\mathrm{sub}(a) = a,$$

then there is no problem in checking that a satisfies 8.5(ii) *and conversely*. So the range of sub picks out exactly the finitary projections in view of 8.5.

Finally, to prove that sub is a finitary projection of $(E \to E)$, we invoke 6.11 and remark that, in view of 8.2, the fixed point set (range) of sub is in a one-one inclusion-preserving correspondence with the domain $\{D \mid D \lhd E\}$. $\square$

These results have almost completely translated the theory of $\lhd$-subdomains into λ-calculus via the sub-combinator. One last step will complete the passage, and then we shall be able to return to solving domain equations.

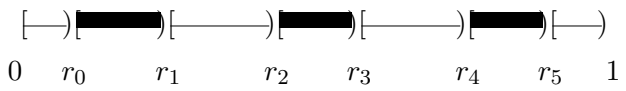
3.9.8 Definition 8.7 — interval presentation of U

DEFINITION 8.7. Let $\mathbb{Q}$ be the set of rational numbers, and let

$$[0,1) = \{q \in \mathbb{Q} \mid 0 \le q < 1\},$$

and similarly for $[r,s)$ for any $r < s$ in $\mathbb{Q}$. The neighbourhood system $\mathcal{U}$ over $[0,1)$ is the set of all non-empty finite unions of rational intervals $[r,s)$ with $0 \le r < s \le 1$. $\square$

A picture of a typical element of $\mathcal{U}$ could be drawn like this:



Note that any union can be taken as a *disjoint* union of the form

$$\bigcup_{i\leq n}[r_{2i}, r_{2i+1})$$

where $0 \leq r_0 < r_1 < r_2 < \cdots < r_{2n} < r_{2n+1} \leq 1$. (Hint: Any overlapping intervals or abutting intervals can always be combined into one long interval.) It is a most elementary exercise to show that, by virtue of this representation, the system $\mathcal{U}$ has a computable presentation. (Some isomorphic versions of $\mathcal{U}$ — equally effective — are recorded in the exercises.) Note that $\mathcal{U}$ has no minimal neighbourhoods: every set in $\mathcal{U}$ can be written as the union of two disjoint sets in $\mathcal{U}$. (Hint: Use the density of the ordering of $\mathbb{Q}$.) The significance of $\mathcal{U}$ can now be explained.

3.9.9 Theorem 8.8 — universality of U

THEOREM 8.8. The system $\mathcal{U}$ is universal in the sense that, for every countable neighbourhood system $\mathcal{D}$, we have

$$\mathcal{D} \trianglelefteq \mathcal{U}.$$

Moreover, if $\mathcal{D}$ is effectively given, then the projection pair making the embedding can be taken as computable. Indeed there is a correspondence between effectively presented domains and the computable, finitary projections of $\mathcal{U}$.

Proof: As $\mathcal{D}$ is countable, we can assume that

$$\mathcal{D} = \{X_n \mid n \in \mathbb{N}\},$$

where $\mathcal{D}$ is a system over a set Δ (say, $X_0 = \Delta$). We shall do the effective and general cases together, where for the latter all remarks on recursiveness are just left out. So, if we want $\mathcal{D}$ effectively given, the above enumeration should be taken as the computable presentation.

Without loss of generality we can assume $\mathcal{D} \cong \mathcal{D}^\dagger$, since otherwise we would just replace $\mathcal{D}$ by $\mathcal{D}^\dagger$. The advantage of this preparation is that unions in $\mathcal{D}^\dagger$ keep things rather *separate* (as we noticed in constructing $\mathbb{P}\mathcal{D}$). In particular, we can be sure of this equivalence:

$$(\blacklozenge) \qquad X_m \subseteq \bigcup_{i<k} X_{n_i} \quad \text{iff} \quad \exists i < k.\, X_m \subseteq X_{n_i}.$$

This property, for example, fails for the system $\mathcal{U}$ as presented in Definition 8.7. However, that observation is of no moment, because we are employing the assumption with respect to $\mathcal{D}$ not $\mathcal{U}$.

The reason for the assumption is this: for $\delta \in \{+,-\}$ define for $X \in \mathcal{D}$:

$$\begin{aligned} \delta X &= X \qquad \text{if } \delta = +; \\ &= \Delta \setminus X \quad \text{if } \delta = -. \end{aligned}$$

(A similar notation will be used for $Y \in \mathcal{U}$.) Then for $\delta \in \{+,-\}^n$ the sets of the form

$$\bigcap_{i<n} \delta_i X_i \quad (= X_\delta, \text{ for short})$$

form a partition of Δ into (at most) 2^n parts. The reason for assumption ($\blacklozenge$) is that we can effectively decide for each $\delta \in \{+,-\}^n$ whether one of these intersections is empty or not. (Why? — assuming that $\mathcal{D}$ is effectively given, of course). If for some reason we had not wanted to pass to $\mathcal{D}^\dagger$, we could have made this stronger assumption of decidability on the (positive) system $\mathcal{D}$. ($\mathcal{U}$, for example, satisfies it.)

Suppose, corresponding to $X_0, X_1, \ldots, X_{n-1}$, we have selected $Y_0, Y_1, \ldots, Y_{n-1} \in \mathcal{U}$ so that, for all $\delta \in \{+,-\}^n$,

$$(\blacksquare) \qquad \bigcap_{i<n} \delta_i X_i = \emptyset \quad \text{iff} \quad \bigcap_{i<n} \delta_i Y_i = \emptyset.$$

We wish to show - effectively - how to choose Y_n corresponding to X_n, so that ($\blacksquare$) holds with $n+1$ replacing n. Proceeding inductively, we obtain a recursive enumeration of sets $Y_n \in \mathcal{U}$ so that

$$\mathcal{D} \equiv \{Y_n \mid n \in \mathbb{N}\} \lhd \mathcal{U}.$$

Clearly the isomorphism (matching X_i to Y_i) will be computable and the projection is computable. (It will then remain only to consider the arbitrary finitary computable projection to complete the proof of the theorem.)

So, consider X_n; for each $\delta \in \{+,-\}^n$ there are four cases:

$$\begin{aligned} X_\delta \cap X_n = \emptyset, \quad X_\delta \cap -X_n = \emptyset, \\ X_\delta \cap X_n \neq \emptyset, \quad X_\delta \cap -X_n \neq \emptyset. \end{aligned}$$

Corresponding to X_δ is a similar intersection Y_δ. If X_δ were $\emptyset$, then Y_δ would be also. If not, $Y_\delta \subseteq [0,1)$ is a union of rational intervals that can be written down explicitly. (Why?) In our four cases on X_n, the first implies the fourth. (Why?) Thus, we need only make some choices in these circumstances:

$$\begin{aligned} X_\delta \cap X_n = \emptyset &: \text{choose } I_{\delta,n} = \emptyset; \\ X_\delta \cap -X_n = \emptyset &: \text{choose } I_{\delta,n} = Y_\delta; \\ \text{otherwise} &: \text{choose } I_{\delta,n} \subseteq Y_\delta, \text{ with } \emptyset \neq I_{\delta,n} \neq Y_\delta. \end{aligned}$$

All these cases are decidable by assumption on $\mathcal{D}$, and the effective choice of (unions of) intervals is effective by construction of $\mathcal{U}$. Now set

$$Y_n = \bigcup_{\delta \in \{+,-\}^n} I_{\delta,n} \neq \emptyset.$$

The set $Y_n \in \mathcal{U}$, it can be found effectively, and ($\blacksquare$) is obviously satisfied for $n+1$.

Finally, suppose that a is a computable, finitary projection of $\mathcal{U}$. As we have seen in the proof of 8.5, the domain corresponding to the range of a is isomorphic to the neighbourhood system

$$\{Y \in \mathcal{U} \mid Y \; a \; Y\} \triangleleft \mathcal{U}.$$

Clearly, if a as a set of ordered pairs of neighbourhoods is recursively enumerable, then the above set is also recursively enumerable (because equality between neighbourhoods is decidable). It follows easily that the subsystem is effectively given as a neighbourhood system in its own right. □

We have now proved that $\mathcal{U}$ is a nice and big domain that is nicely behaved with respect to computable mappings. It has some very interesting subdomains; to name a few:

$$\mathcal{U}+\mathcal{U}, \quad \mathcal{U}\oplus\mathcal{U}, \quad \mathcal{U}\times\mathcal{U}, \quad \mathcal{U}\otimes\mathcal{U}$$

$$\mathcal{U}_\perp, \quad \mathcal{U}^\infty, \quad \mathcal{U}^\S, \quad \mathbb{P}\mathcal{U}, \quad \mathcal{U}\to\mathcal{U}$$

That all of these are $\trianglelefteq \mathcal{U}$ follows from knowing that they are all effectively presented. What we wish to check next is that they all combine well with respect to projections. To this end the explicit definitions are given for the constructs $+$, $\times$, and $\to$, and the details of the others are left for the exercises.

DEFINITION 8.9. Let the computable projection pairs $i_+ : \mathcal{U}+\mathcal{U} \to \mathcal{U}$ and $j_+ : \mathcal{U} \to \mathcal{U}+\mathcal{U}$ be fixed. Similarly choose $i_\times, j_\times$ and $i_\to, j_\to$ for $\mathcal{U}\times\mathcal{U}$ and $\mathcal{U}\to\mathcal{U}$. Define:

$$a + b = \mathrm{cond} \circ \langle \mathrm{which}, i_+ \circ \mathrm{in}_0 \circ a \circ \mathrm{out}_0, i_+ \circ \mathrm{in}_1 \circ b \circ \mathrm{out}_1 \rangle \circ j_+ \; ;$$

$$a \times b = i_\times \circ \langle a \circ \mathrm{proj}_0, b \circ \mathrm{proj}_1 \rangle \circ j_\times \; ;$$

$$a \to b = i_{\to} \circ (\lambda f.\, b \circ f \circ a) \circ j_{\to}\ ,$$

for all $a, b : \mathcal{U} \to \mathcal{U}$. □

These interesting(computable!) combinators on elements of $\mathcal{U} \to \mathcal{U}$ have many, many properties. We shall, however, only see what they do to projections.

PROPOSITION 8.10. If $a, b : \mathcal{U} \to \mathcal{U}$ are projections, then so are $a + b$, $a \times b$, and $a \to b$. If a and b are finitary, then so are the others; for the fixed-point set of each of them is isomorphic to the corresponding construct applied to the domains determined by a and b.

Proof: Suppose that $a, b \sqsubseteq I_{\mathcal{U}}$ (= I for short). Then

$$a + b \sqsubseteq I + I = i_+ \circ j_+ \sqsubseteq I.$$

The other cases are similar.

Suppose $a = a \circ a$ and $b = b \circ b$, then, for example,

$$\begin{aligned}(a \times b) \circ (a \times b) &= i_\times \circ \langle a \circ \mathrm{proj}_0,\ b \circ \mathrm{proj}_1 \rangle \circ \langle a \circ \mathrm{proj}_0,\ b \circ \mathrm{proj}_1 \rangle \circ j_\times \\ &= i_\times \circ \langle a \circ a \circ \mathrm{proj}_0,\ b \circ b \circ \mathrm{proj}_1 \rangle \circ j_\times \\ &= a \times b.\end{aligned}$$

The other cases are similar.

Now in case the fixed-point sets of a and b are domains, they are respectively isomorphic to

$$D_a = \{X \in \mathcal{U} \mid X\ a\ X\} \quad \text{and}$$
$$D_b = \{Y \in \mathcal{U} \mid Y\ b\ Y\}.$$

We have to show, for example, that

$$D_a \to D_b \cong D_{a \to b}.$$

Now to simplify matters, remark that the fixed-point set of $a \to b$ on $\mathcal{U}$ is isomorphic to the fixed-point set of $\lambda f.\ b \circ f \circ a$ on $(\mathcal{U} \to \mathcal{U})$. (Hint: use $i_\to$ and $j_\to$ to set up the isomorphism.) So we have to think what it is for an $f : \mathcal{U} \to \mathcal{U}$ to satisfy

$$f = b \circ f \circ a.$$

Notice that we might as well say that $a : \mathcal{U} \to D_a$ and that this map is the other half of an obvious projection pair where

$$i_a : D_a \to \mathcal{U},$$

and $i_a \circ a = a$ and $a \circ i_a = i_a$. So if $g : D_a \to D_b$, let

$$f = i_b \circ g \circ a;$$

then $b \circ f \circ a = f$. Conversely, if f is like this, then let

$$g = b \circ f \circ i_a.$$

Thus, $i_b \circ g \circ a = b \circ f \circ a = f$; so there is an order-preserving isomorphism between the $g : D_a \to D_b$ and the $f = b \circ f \circ a$.

The isomorphism proofs for $+$ and $\times$ are similar. $\square$

Well, this was a lot of work, but the pay-off is rather handsome. What we have done is transpose all the

$$D_a \triangleleft U$$

over to finitary projections $a : U \to U$. This transposition is an isomorphism, because

$$D_a \triangleleft D_b \text{ iff } a \sqsubseteq b.$$

Moreover, by the method of 8.9 and 8.10, all our favourite constructs have been made into *combinators*, that is, approximable — even computable — maps on the domain of finitary projections. *ALL APPROXIMABLE (COMPUTABLE) MAPS HAVE (COMPUTABLE) FIXED POINTS.* And there you are! The standard fixed-point method is available to obtain computable (i.e. effectively given) solutions to *all* domain equations (even sets of equations) where the constructs can be reworked in *this* way to be defined on projections. Examples are suggested in the exercises.

Another pay-off concerns the λ-calculus itself. Inasmuch as

$$U + U, \quad U \times U, \quad U \to U \triangleleft U,$$

we might just as well forget the outside world and regard all these useful domains as being part of U. For example, on the left we have the new notation and on the right the old notation:

$$\begin{aligned}
\mathrm{which}(z) &= \mathrm{which}(j_+(z)); \\
\mathrm{in}_i(x) &= i_+(\mathrm{in}_i(x)), \quad i = 0, 1; \\
\mathrm{out}_i(x) &= \mathrm{out}_i(j_+(x)), \quad i = 0, 1; \\
\langle x, y \rangle &= i_\times(\langle x, y \rangle); \\
\mathrm{proj}_i(z) &= \mathrm{proj}_i(j_\times(z)), \quad i = 0, 1; \\
u(x) &= j_\to(u)(x); \\
\lambda x.\, \tau &\cong i_\to(\lambda x.\, \tau).
\end{aligned}$$

And, there is no reason to stop here. The system

$$T \cong \{\{0, 1/2\}, \{1/2, 1\}, \{0, 1\}\} \triangleleft U,$$

so we might as well think of

$$\text{true, false} \in |U|$$

and think of $\mathrm{cond} : U \times U \times U \to U$. No! that is wrong: under the new regime *EVERYTHING IS AN ELEMENT OF U*. With the new meaning of λ, all functions, all pairs, all combinators, all constructs become elements of U.

It takes a little time to get used to "universal conscription" with all elements doing (at least) double duty in the same domain, but there are many advantages, both notational and conceptual.

3.9.12 Lecture VIII exercises

EXERCISES

3.9.13 Exercise 8.11 — retraction on intervals

Let $\mathbb{Q}$ be the set of rational numbers and define a neighbourhood system by the equation

$$R = \{[0, r) \mid r \in \mathbb{Q} \text{ and } 0 < r \leq 1\}.$$

Show that the following defines an approximable map $a : R \to R$:

$$[0, r)\ a\ [0, s) \quad \text{iff} \quad r < s \text{ or } r = s = 1.$$

Show in addition that a is a projection where the fixed-point set of a is in a one-one correspondence with the *real* numbers between 0 and 1 inclusive. (Hint: Recall Dedekind cuts and show $\subseteq$ matches $\leq$.) Conclude that a is *NOT* finitary. (Hint: Aside from $\perp$ there are no finite elements for $\{x \mid x = a(x)\}$.)

Tip summary The tip records that Scott's map `a` on `R` is a projection and is not finitary.

Development Builds the Dedekind-cut system `R` and proves the projection `a` is not finitary.

EXERCISE 8.12. Generalize the notation $2X + 1$ for subsets $X \subseteq \mathbb{N}$ to sets of the form

$$2^k X + \ell, \quad \text{where } \ell < 2^k.$$

Let V be the non-empty finite unions of sets $2^k\mathbb{N} + \ell$. Show that $U \cong V$ and that the isomorphism is effective, thus obtaining another presentation of U.

Tip summary Scott's claim is a single conjunction: V is effectively given, and U is effectively isomorphic to V. The Lean tip `exercise_8_12` packages exactly that, assembling `V_isEffectivelyGiven` with the concrete effective isomorphism `effectiveIso812_UV`.

Development Scott gives no written proof—only the construction of V and the demand that the isomorphism be effective. The formalization therefore supplies a structured development under the exercise: present V, build an abstract domain isomorphism, make it effective, equip both sides with computable bisections/splits, and assemble the effective iso.

Presenting V The integer neighbourhood system V is built from affine residue classes $2^k\mathbb{N} + \ell$ and their non-empty finite unions (`affine` / `levelSet` / `upsample`). Pure neighbourhood facts live under `namespace V` (`V.union_mem`, `V.diff_mem`, `V.isPositive`, ...).

— `V` and Pref-folded neighbourhood lemmas

Its computable presentation (indices, decoding, intersection/union/difference codes, and the canonical bisection `splitV*`) lives in a dedicated library module.

— computable presentation of `V`, including `VComputablePresentation` and `V.isEffectivelyGiven`

Abstract isomorphism (8.12(c)) Given two positive, difference-closed, atomless neighbourhood systems with enumerations that cover every neighbourhood and start at the master set, one builds paired atom sequences (`XPseq`/`YPseq`) from mutual `SplitSpec'` probes and obtains a domain isomorphism. The headline is `isomorphic_812c`.

— difference-closure / no-minimal apparatus, atom pairing, and `isomorphic_812c`

Abstract `E`-side atoms The one-sided atom apparatus against an abstract neighbourhood system `E` (the `atomU` analogue) lives under `atomE`, with Pref-folded companions `atomE.zero`, `atomE.succ`, `atomE.congr`, `atomE.invariant`, ...

— `atomE`, `YseqE`, and Pref-folded `atomE.xxx` lemmas

Computable presentation predicates The data-carrying structures for computable difference, split, union, and bisection each live in their own library module, with Pref-folded companions under the structure namespace.

— `IsComputableDiff` and Diff-side deciders

— `IsComputableSplit`

— `IsComputableUnion` and `combineFound2`

— `ComputableBisection` and bisection-derived splits

Effective isomorphism (8.12(d)) The same back-and-forth is carried out on computable presentations: coded atom sequences, primitivity of the step maps, and the order isomorphism `domainIsoCode812d` lift to an `EffectiveIso`. The generic assembly is `effectiveIso812d`.

— coded pairing, primrec witnesses, and `effectiveIso812d`

Computable split of U against V (8.12(e)) With `U`'s computable difference and V's bisection in hand, `splitX812e` is the concrete `IsComputableSplit` of U probing V (`isComputableSplit.«812e»`).

— `U_isComputableDiff`, `splitX812e`, and `isComputableSplit.«812e»`

Symmetric split and UV assembly (8.12(f)–(g)) The mirror split `splitX812f` (V probing U via `UBisection2`), both `SplitSpec′` halves, computable unions, and the final `EffectiveIso U V` are assembled as `effectiveIso812_UV`.

— «`812f`», `hxSplit812e`/`hySplit812f`, unions, and `effectiveIso812_UV`

The tip then simply pairs effective givenness of V with that isomorphism, which is Exercise 8.12 in Scott's sense.

— Scott tip `exercise_8_12`

3.9.15 Exercise 8.13 — Boolean-algebra filters

(For logicians.) Prove that the universal domain U is isomorphic to the domain of all proper filters of the free Boolean algebra on $\aleph_0$-generators (= the Lindenbaum algebra of propositional calculus). (For topologists.) Connect this

representation of $\mathcal{U}$ with the collection of non-empty open subsets of the product space $2^{\mathbf{N}}$ (= Cantor space).

Tip summary The tip is the isomorphism $U \cong V$, obtained from the effective iso of Exercise 8.12 together with the Boolean-algebra presentation of `V`.

Development Defines the Boolean algebra generated by bit-test generators.

3.9.16 Exercise 8.14 — closure operators

A retraction $a : D \to D$ is called a *closure operator* iff $I_D \sqsubseteq a$. On a domain like $P\mathbf{N}$, give some examples of closure operators. (Hint: Close up a set of integers under addition. Is this continuous on $P\mathbf{N}$?) Prove in general for any closure $a : D \to D$ that the fixed-point set of a is always a finitary domain. (Hint: Show that the fixed-point set is closed under intersections and directed unions.) What are the finite elements of the fixed-point set?

Tip summary The tip states that the fixed-point set of any closure operator is a finitary domain.

Development Defines closure operators and shows `Fix(a)` is a finitary domain.

The tip then assembles those tools into Scott's statement.
— `exercise_8_14`

3.9.17 Exercise 8.15 — domain of subsystems

Give a direct proof that the domain $\{X \mid X \triangleleft D\}$ is effectively presented if D is. (Hint: The finite elements of the domain correspond exactly to the finite systems $X \triangleleft D$.) In the case of $D = \mathcal{U}$, show that the computable elements of the domain correspond exactly to the effectively presented domains (up to effective isomorphism).

Tip summary The tip states that if `D` is effectively given then so is (a presentation of) the domain of its subsystems.

Development Library tools: finitely generated subsystems and the reconstructed system `SubD`.

open DomainTheory.NeighbourhoodSystems NeighborhoodSystem ApproximableMap Domain.
    Recursive

theorem exercise_8_16 {α : Type*} {E : NeighborhoodSystem α} :
    (∀ {a b : ApproximableMap E E}, FinitaryProjection a → FinitaryProjection b →
        (a ≤ b ↔ fixedNbhd a ? fixedNbhd b)) ∧
      (∀ {P : ComputablePresentation E} {a : ApproximableMap E E},
        ComputableMap P P a → (fixedNbhd a).IsEffectivelyGiven) :=
  @exercise_8_16_assembly α E

end
```

EXERCISE 8.16. For finitary projections $a : E \to E$, write

$$D_a = \{X \in E \mid X \sqsubseteq aX\}$$

(cf. 8.5.). Show that for any two such projections $a, b : E \to E$ we have

$$a \sqsubseteq b \quad \text{iff} \quad D_a \lhd D_b.$$

(This fills in the gap at the end of the proof of 8.6.) Also finish off the proof of 8.8 by showing that if E is effectively given and $a : E \to E$ is computable, then D_a is effectively given.

Tip summary The tip packages the order correspondence for finitary projections with the effectivity of their fixed neighbourhoods.

Development Matches the order of finitary projections with subdomain order and records effectivity of `D_a`.

The tip then assembles those tools into Scott's statement.

  ⟨V.isUniversal, prodUU_trianglelefteq_U, sumUU_trianglelefteq_U,
    funSpaceUU_trianglelefteq_U⟩

end
```

EXERCISE 8.17. Find explicitly (if possible) the projection pairs for $\mathcal{U}+\mathcal{U}$, $\mathcal{U}\times\mathcal{U}$, and $\mathcal{U}\to\mathcal{U}$ needed for 8.9. Are any of these domains isomorphic with $\mathcal{U}$? (The author does not know a really good construction for $\mathcal{U}\to\mathcal{U}$.) Find a universal domain $V\neq\mathcal{U}$.

Tip summary The tip asserts universality of `V` together with the product/sum/function-space embeddings into `U`.

Development Proves `V` is universal and records the standard embeddings into `U`.
— `ProjPair` and composition/iso/subsystem constructors
— universality and the concrete `U`/`V` embeddings
The tip then assembles those tools into Scott's statement.
— `exercise_8_17`

3.9.20 Exercise 8.18 — missing proofs of 8.10

`Exercise_8_18.lean`

theorem exercise_8_21 {a : ApproximableMap U U} (ha : FinitaryProjection a) :
    FinitaryProjection (aSharp a) :=
  isFinitaryProjection_aSharp ha

end
```

EXERCISE 8.21. Using the fixed-point construction, show that there is a continuous and computable operator $\lambda a.\, a^{\S}$, such that if a is a finitary projection of U, then

$$D_{a^{\S}} \cong (D_a)^{\S} .$$

Tip summary The tip asserts that the sharp of a finitary projection is again a finitary projection.

Development Develops the sharp construction and shows it yields a finitary projection.
— `aSharp` projection/computability companions and Ex 8.25 closing
The tip then assembles those tools into Scott's statement.
— `exercise_8_21`

3.9.24 Exercise 8.22 — comparing B and C

Which of the two relations hold:

$$B \trianglelefteq C \quad \text{or} \quad C \trianglelefteq B \,?$$

Or do they both hold? In general if we use domain equations

$$D = T(D) + S(D) , \quad \text{and}$$

$$E = T(E) ,$$

will $E \trianglelefteq D$ hold? What projections do you see in the examples in 6.2?

Tip summary The tip asserts the concrete embedding relation between Scott's examples `C` and `B`.

Development Compares Scott's concrete examples `B` and `C`.

EXERCISE 8.23. Suppose a construct T on domains can be made into a computable operator $t : (U \to U) \to (U \to U)$ so that whenever $a : U \to U$ is a finitary projection, then so is $t(a)$ and

$$D_{t(a)} \cong T(D_a) .$$

Does it follow that $\|t\| = \mathrm{fix}(t)$ is such that

$$D_{\|t\|} \cong T(D_{\|t\|})$$

really is the initial solution of the domain equation with respect to projections? Since t is computable, will this solution be effectively given?

Tip summary The tip asserts that `fixOp t` is a finitary projection whenever `t` preserves them.

Development Defines `fixOp` and proves it is finitary when the transformer preserves finitary projections. The tip then assembles those tools into Scott's statement.

    (s t : ApproximableMap (PairSpace (E := E)) (funSpace E E))
    (hst : ∀ a b, FinitaryProjection a → FinitaryProjection b →
      FinitaryProjection (binOp s a b) ∧ FinitaryProjection (binOp t a b)) :
    FinitaryProjection (aStar s t) ∧ FinitaryProjection (bStar s t) :=
  isFinitaryProjection_aStar_bStar s t hst

end
```

EXERCISE 8.24. Suppose S and T are two (binary-argument) constructs on domains that can be made into computable operators on projections of the universal domain. Show that we can therefore find a pair of effectively presented domains such that

$$D \cong S(D, E) \quad \text{and} \quad E \cong T(D, E).$$

Tip summary The tip asserts that the coupled solutions `aStar`, `bStar` are finitary projections.

Development Solves the coupled domain equations with finitary projections `aStar`, `bStar`. The tip then assembles those tools into Scott's statement.
— `exercise_8_24`

3.9.27 Exercise 8.25 — reflexive function space

The problem is to find non-trivial solutions to the domain equation

$$(\spadesuit) \qquad D \cong D \to D.$$

Show that the "obvious" solution by retracts is of no use because

$$1 \to 1 = 1$$

for projections. Change the method as follows. Show first

$$U^\infty \times U^\infty \cong U^\infty.$$

Next solve

$$D \cong D \to U^\infty$$

and remark that $U \lhd D$; so D is universal and non-trivial. Finally prove (♠) for this D. (Hint: First show

$$D \times D \cong D,$$

and then show D satisfies (♠).) Is this D effectively given?

Tip summary The tip asserts existence of a non-trivial domain isomorphic to its function space and containing `U`.

Development Rational-interval coding used by effective presentations.

Builds a non-trivial reflexive domain $D \cong D \to D$ containing `U`.
The tip then assembles those tools into Scott's statement.
— `exercise_8_25`

3.9.28 Exercise 8.26 — untyped calculus in U

Discuss in more detail the "pay-off" for U, namely the translation of "untyped" λ-calculus into U as shown by the equations at the end of the lecture after the proof of 8.9. In particular show how the whole of the **typed** λ-calculus can be retranslated back into U with the aid of projections. (Hint: Whenever you want to write

$$f : D_a \to D_b,$$

write instead

$$f = b \circ f \circ a,$$

where a, b are finitary projections. Whenever you want to form a λ-abstraction

$$\lambda x^{D_a}.\, \sigma,$$

where σ is of type D_b, instead form

$$\lambda x.\, b(\sigma'[a(x)/x]),$$

where σ' is the further translation of σ into untyped λ-calculus. Be sure to show that this result "has the right type" in the sense defined above.)

Tip summary The tip asserts β-soundness of the self-hosted encoding: `Uapply (Ulam f) x = f(x)`.

Development Encodes self-application and self-abstraction inside `U` and proves β-soundness.

The tip then assembles those tools into Scott's statement.
— `exercise_8_26`

3.9.29 Exercise 8.27 — infinite cartesian products

(Suggested by James Donahue.)

Finite cartesian products of domains are formed by the $D_0 \times D_1$-construct we have used so often. The problem is to define — computably — some *infinite* cartesian products. In particular, as applied to the universal domain U, the combinator `sub` is to be regarded as a finitary projection of U whose fixed points are exactly *all* the finitary projections. A map

$$d = \mathrm{sub} \circ d \circ \mathrm{sub}$$

can be regarded as a *polymorphic type* (because, whenever t is a finitary projection (= type), then so is $d(t)$). The *continuous product* of *all* these types would be the domain of all approximable functions x such that

$$x(t) = d(t)(x(t))$$

for all types t. (Why does this equation mean that x is in the product?) Define Π as a combinator by

$$\Pi = \lambda d\, \lambda x\, \lambda t.\, \mathrm{sub}(d(\mathrm{sub}(t)))(x(\mathrm{sub}(t))).$$

Show that for d a polymorphic type, $\Pi(d)$ is a type. (Hint: It is easy to check that $\Pi(d)$ is a projection; the problem is to show it is *finitary*.)

Tip summary The tip asserts that for any polymorphic type `d`, $\Pi(d)$ is a finitary projection.

Development Defines polymorphic types and proves the `piD` side of finitariness.

4 Information Systems (1982)

The purpose of the theory of domains is to give models for spaces on which to define computable functions. The kinds of spaces needed for denotational semantics involve not only spaces of higher type (e.g. function spaces) but also spaces defined recursively (e.g. reflexive domains). Also required are many special domain constructs (or functors) in order to create the desired structures. There are several choices of a suitable category of domains, but the basic one which has the simplest properties is the one sometimes called *consistently complete algebraic* cpo*'s*. This category of domains is studied in this chapter from a new, and it is to be hoped, simpler point of view incorporating the approaches of many authors into a unified presentation. Briefly, the domains of elements are represented set theoretically with the aid of structures called *information systems*. These systems are very familiar from mathematical logic, and their use seems to accord well with intuition. Many things that were done previously axiomatically can now be proved in a straightforward way as theorems. The present chapter discusses many examples in an informal way that should serve as an introduction to the subject.

Dependencies. Each box is one folder. The arrowhead points at the folder that imports, and the number is how many direct imports.

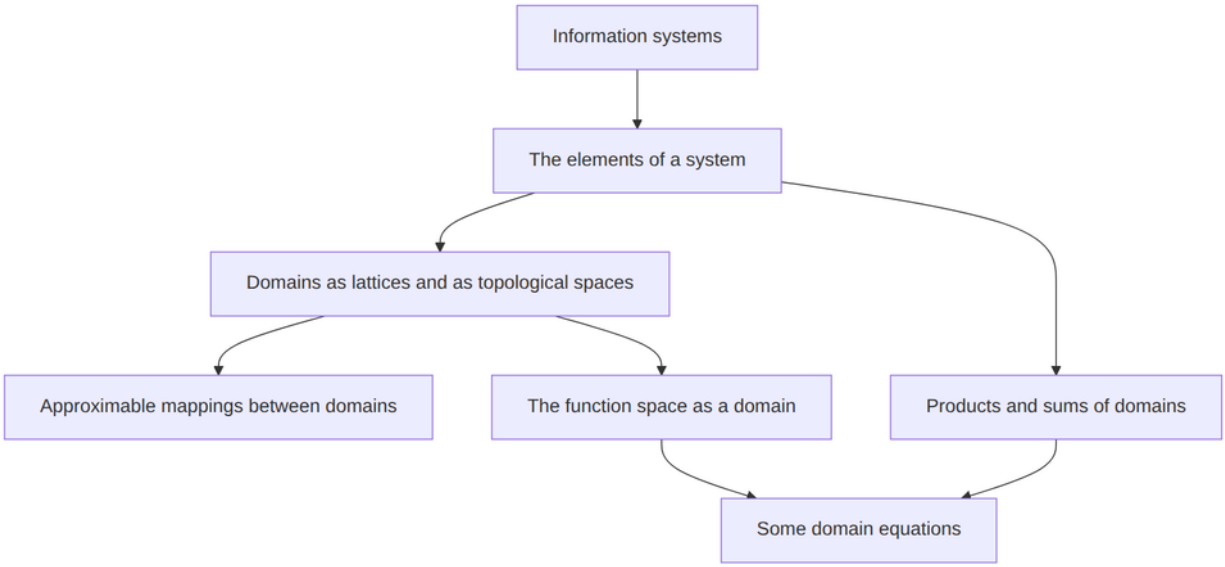

Figure 47: Information Systems (1982).

4.1 Introduction

The difficulty in the presentation of the subject is in justifying the level of abstraction used in comparison with the payoff: too often the effort needed for understanding the abstractions does not seem worth the trouble—especially if the notions are unfamiliar or excessively general.

For example, Category Theory, which is much used in discussions of the Theory of Domains, seems far too abstract to many people. On the other hand, Automata Theory—which has often benefited from some use of Category Theory—is quite abstract and, in many aspects perhaps, quite useless, but the level of abstraction is fairly low and the reasons for the definitions are usually evident. Thus, the subject has become by now a standard topic even for undergraduate courses. Michael Rabin and Scott had much to do with

influencing the subsequent development of the theory by formulating some years ago some basic concepts (many previously known) in a way that made sense to anyone who had been exposed to a little Abstract Algebra, Logic and Set Theory. This expository part of their paper did not require originality, but rather a certain frame of mind and a certain style of writing to put the ideas and problems in sharp relief. (The original paper is Rabin-Scott [1959]; see the excellent historical review of the subject in Greibach [1981].)

Lattices are very familiar to logicians and those interested in Universal Algebra. But it takes some time to learn the special terminology and to become comfortable with the necessary examples. Indeed, without a stock of examples, it is impossible to have sufficient intuition for making the required constructions. True, some people took to the approach, and the lattice-theoretic definitions were simple enough to motivate. But a much greater percentage of people Scott came in contact with found the large number of things to learn a definite roadblock to understanding. And the Lattice Theory was only partly standard, since this approach to the theory has to employ complete lattices and topological notions in order to explain *limits* and *continuity* adequately. In fact, Topology of a rather mathematically simple set-theoretical kind could have been used as the whole foundation much as in Scott [1972], but that kind of mathematics seems even less attractive to computer scientists. Nevertheless, the lattice-theoretic approach has great consistency and coherence; it has been carried out in full detail in Gierz, *et al.* [1980], which also gives the topological connections. That book contains a large number of references to the mathematical literature to show the connections of the theory to many other topics. What we had to miss out there is a clear hook-up with computability theory, owing simply to a lack of space and time to be able to cover everything.

In Scott [1981], Scott tried out another, different presentation (which is also explained in Scott [1982].) However, Scott found that the use of *neighborhood systems* causes confusion in people not used to thinking in terms of sets of sets of sets of sets . . . , even though the set theory required is quite simple. This section tries out another plan for making the story easy and natural. The notion to be used we call an *information system*. This is a "static" notion appropriate to bodies of information about coherent groups of elements. The "dynamic" ideas enter in the ways different systems can be related and in the semantical definitions about meanings of programming language constructs. (For discussions of semantical definitions see Stoy [1977], Gordon [1979], and Tennent [1981].) Neighborhood systems are, in a precise sense, equivalent to information systems, but there seems to be an interesting trade-off between what properties of structures are *axiomatized* and what are *implicit* in the form of the structure. Perhaps, despite their simplicity, neighborhoods leave too much implicit, too much to be extracted by definition; information systems, on the other hand, do seem to be more flexible in doing several of the important constructions. It all comes down to just where one imposes the closure conditions on the structures. Information systems give the right mix of axioms *vs.* definitions.

Another word about Category Theory: it is particularly significant and important for the theory and for the whole area of semantics. But it must be approached with great caution, for the sheer number of definitions and axioms can try the most patient reader. It is especially necessary in discussing applications of abstract mathematical ideas to keep the motivation strongly in mind. This is often hard to do if the categories get too thick, but of course it all depends on the writer. Category Theory is especially useful in stating *general* properties of structures and in *characterizing* constructions uniquely; however, there often is a problem actually justifying the *existence* of certain constructions, and a direct approach can be quicker than quoting lots of theorems. But, man cannot live by construction alone: theorems have to be proved in order to get the proper value out of the work. Domain Theory must also be convenient for demonstrating the soundness of various proof rules for properties of recursively defined objects and recursively defined domains. Category Theory can be helpful here. A step in the right direction has been made in the LCF system (see Gordon-Milner-Wadsworth [1979]), which, however, does not take advantage of general Category Theory.

The main purpose of the Theory of Domains in Denotational Semantics is to give a mathematical model of a system of *types*—including function-space types—and to explain a notion of computability with respect to these types. There are many possible theories of types, but the construction of domains is meant to justify recursive definitions at all types, and—most essentially—to justify recursive definitions of types. Pursuing these goals has certain consequences, as we shall see. The model presented here is only one approach, and some comparisons with other methods will be made. Again some help from Category Theory would be welcome in comparing the different kinds of modelling.

One benefit of Domain Theory is that it is possible to make sense of types containing *infinite* elements. The cost required seems to be that the domains therefore have to contain *partial* elements as well as *total* elements. And this is where the lattice-theoretic definitions entered in the earlier presentations: the partial ordering with relations like $x \sqsubseteq y$ was used to express the fact that the element x was "less defined" (i.e. more partial) than y but "contained in" y. The relation $\sqsubseteq$, however, must be subjected to many axioms to have a theory suitable to the desired applications. Instead of such a big group of axioms, we put forward here a construction where the "skeleton" (or better: "backbone") of a domain is introduced by just a few axioms. Then the domain itself is defined as a certain construct from the backbone in order to define the appropriate notion of element. There are several advantages to this approach:

- Simple definitions of the basic concepts can be given.
- Detailed properties are proved as theorems rather than assumed as axioms.
- Emphasis can be given to the constructive nature of the definitions.
- Domains can be made more visible.
- The theory of domains is made more available for applications, because it is easier to produce the needed complex domains.

4.2 Information systems

Dependencies. Inside InformationSystems, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

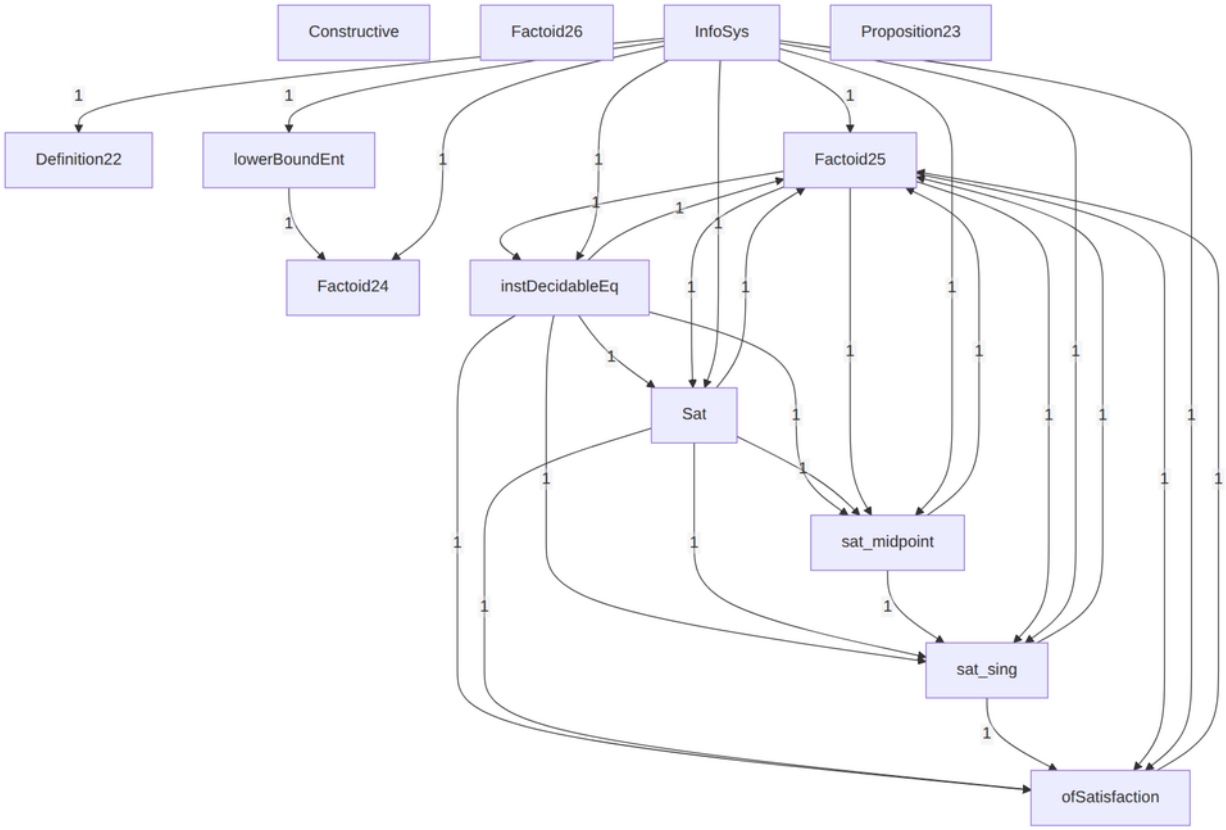

Figure 48: Information systems.

Intuitively, an information system is a set of "propositions" that can be made about "possible elements" of the desired domain. We will assume that sufficiently many propositions have been supplied to distinguish between distinct elements; as a consequence, an element can be constructed abstractly as the set of all the propositions that are true of it. Partial elements have "small" sets; while total elements have "large" sets (even: maximal). To make this somewhat rough idea precise, we have to explain—by a suitable, but small choice of axioms—how the collection of all propositions relevant to the domain hangs together, or better, is structured as a set of abstract propositions. Fortunately, the axioms for this structure are very simple and familiar, which is a great help in making up examples.

- Definition 2.1
- A first example
- A second example
- A third example
- Definition 2.2
- Proposition 2.3

So much for the definition of what an information system is as a mathematical structure. The next question is: What is it good for? More precisely, if information systems are the backbones of domains, then where are the elements? That is the topic of the next section.

4.3 The elements of a system

Dependencies. Inside ElementsOfASystem, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

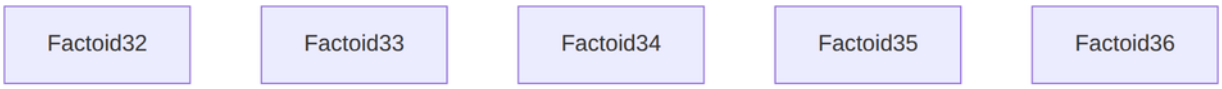

Figure 49: The elements of a system.

Let $\mathbf{A}$ be an information system, and suppose we already had a concept of being an element of $\mathbf{A}$. The data objects are meant to be propositions about elements, so if X is in $D_{\mathbf{A}}$ and if x is an element, then we can be expected to know what it means to say that X is true of x. Since all we are given is the set of data objects $D_{\mathbf{A}}$, we have to assume that it contains enough objects to distinguish between distinct elements.

(If there were not enough of them, we would have to change the set $D_{\mathbf{A}}$.) Formally, we can write of two elements x and y:

$$x = y \quad \text{iff all } X \in D_{\mathbf{A}} \text{ which are true of } x \text{ are also true of } y, \text{ and conversely.}$$

If this principle is accepted, then the elements can be *identified* with the sets of propositions true of them; formally we can assert:

$$x = \{X \in D_{\mathbf{A}} \mid X \text{ is true of } x\}.$$

There can be no confusion injected here in identifying elements that ought to be distinct, since we are assuming that there are enough data objects in the system. If for some reason we felt we ought to have more of them to distinguish between more elements, then we would have to pass to a larger and *different* information system. By agreement, then, the above equation is a tautology. So, for the sake of simplicity, elements can be taken to be *sets* of data objects. But, we hasten to ask, which sets? The question is really: What are the properties of truth? The answers are well known, and, in fact, we have already used them in our examples in the last section. In words, the set of true propositions about a possible element must be (i) consistent in itself, and (ii) closed under entailment (or *deductively closed*, for short). Condition (i) is clear because we are talking about a *possible* element, not an impossible one. Condition (ii) is acceptable, because, by the very meaning of the word, entailment should be truth preserving. In addition, we are also saying the converse: *any* set having properties (i) and (ii) corresponds to a (partial) element. Here is the formal statement:

4.4 Domains as lattices and as topological spaces

Dependencies. Inside DomainsAsLatticesAndAsTopologicalSpaces, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 50: Domains as lattices and as topological spaces.

I will attempt to keep this section as informal as possible—especially as Sections 2 and 3 were quite formal (i.e. mathematical) enough. The main purpose of the discussion of this section is to relate the new presentation of the Theory of Domains to previously published ones. (Some alternatives are discussed at the end of the paper.)

Lattice-theoretic considerations. Let $\mathbf{A}$ be an information system. Because the elements of $|\mathbf{A}|$ are introduced as sets, these elements can be given structure from what we know already about ordinary sets. For instance, the set-theoretic inclusion relation between sets can certainly be applied to elements. The question is: What does $x \subseteq y$ mean intuitively? In fact, we have already mentioned this relationship before. It means that every proposition (among the ones given by the information system) true of x is also true of y (though not necessarily conversely). In other words, x is perhaps only partially determined, while y is more fully determined in a way that includes everything true of x. Clearly, then, if we grant the interest of partial elements, then this relation is a natural and basic one. We often read "$x \subseteq y$" as "x approximates y".

Now here is one of the main points of the new exposition: Because $x \subseteq y$ is *defined* in terms of a familiar mathematical notion, then as a relation between elements it inherits all the well-known properties of the set-theoretical relation. It should not be necessary to write them out, for everyone who can read this far knows that $\subseteq$ is in particular reflexive and transitive. We say that the domain $|\mathbf{A}|$ is a *partially ordered set under inclusion*. We note that this (trivial) result is *proved* from the definition rather than assumed as an axiom.

Let us try out another notion. Elements are consistent, deductively closed sets of data objects. Right? Every subset of a consistent set is consistent, but not every subset is closed under entailment, in general. Right? But suppose that x and y are two elements. It can easily be seen that their intersection $x \cap y$ is again consistent and deductively closed (by a 2 nanosecond proof). Therefore, the set of elements of a domain is closed under intersection. This means that, as a partially ordered set, $|\mathbf{A}|$ is an *inf semilattice*.

Well, the exact terminology is quite unimportant, but the properties of $\cap$ when combined with the properties of $\subseteq$ are pleasantly "algebraic" (and run to several lines when written out). We all know them: $\cap$ is idempotent, commutative, and associative. The element $\bot$, being the The element $\bot$, being the smallest element of the domain, is a zero element for $\cap$. The operation $\cap$ is monotonic with respect to $\subseteq$, and we have the connection:

$$x \subseteq y \text{ iff } x \cap y = x.$$

What has just been alluded to in words is the standard mathematical axiomatization of the properties of an infimum (or meet) operation in a partially ordered set. (Remember, however, to have an operation well defined within a set it is necessary also to have closure under that operation.)

What about infs of subsets? No problem. For any *non-empty* subfamily of $|\mathbf{A}|$, it is just as easy to prove that the set-theoretical intersection of all the elements in the subfamily is again an element of the domain. This makes $|\mathbf{A}|$ a (conditionally) complete inf semilattice. Even if you do not have any idea what I am talking about, it does not matter because the properties of the domain are built in by the very definition; you do not have to worry *at the start* about their formulation, for you can prove them when you need them (if ever).

What about suprema (or sups or joins)? Here there is a slight problem, because in the way we set things up they *do not* always have to exist. Consider what happens with just two elements x and y. The set-theoretical union of the two elements as subsets of $D_{\mathbf{A}}$ need be neither consistent nor deductively closed; and even if $x \cup y$ is consistent, it need not be closed under entailment. So if we want sups *within* $|\mathbf{A}|$, we cannot get by as cheaply as we can with a domain of arbitrary sets for which the simple union is the answer.

Let us write the sup (supposing it exists in $|\mathbf{A}|$) as $x \sqcup y$. What do we have when we actually have it? By the lore of partially ordered sets, $x \sqcup y$ must be the *least element* in $|\mathbf{A}|$ which includes (in the sense of $\subseteq$) both x and y. Now we have just spoken about infs of families of elements: they exist if the family is non-empty. This indicates that $x \sqcup y$ exists exactly when there is at least one element z in $|\mathbf{A}|$ such that $x \subseteq z$ and $y \subseteq z$. This turns out to be a way to say—entirely inside $|\mathbf{A}|$—that $x \cup y$ is consistent. In other words (and more generally) a sup of a subfamily exists if, and only if, the union of the family is consistent. (And in that case the sup is just the deductive closure of the union—that is, it is generally larger than the simple set-theoretical union.) This has an axiomatic version, but it is slightly complicated by the fact that sups do not always exist. In case $\top_{\mathbf{A}}$ exists, then we always have all the sups, and $|\mathbf{A}|$ is a *complete lattice*. (This is discussed in full axiomatic splendor in Gierz, et al. [1980].) But, let it hasten to be added, not every complete lattice is isomorphic to a domain. The lattices that correspond to domains are the so-called *algebraic lattices*. (See the discussion loc. cit. for the additional axiomatics required.) When the top is missing, the partially ordered structures corresponding to domains are called *conditionally complete, algebraic cpo's*.

There is, however, an important case in $|\mathbf{A}|$ where the union is consistent and is, in fact, the sup in the domain. Suppose we have a sequence of elements such that

$$x_0 \subseteq x_1 \subseteq x_2 \subseteq \cdots \subseteq x_n \subseteq x_{n+1} \subseteq \cdots$$

As n increases, we can say that the elements x_n are getting "better and better"; thus, they must be approaching something even more desirable *in the limit*. Let

$$y = \bigcup_{n=0}^{\infty} x_n,$$

then there is no question that y is a subset of $D_{\mathbf{A}}$. But is it an element? Consistency, recall, means that every *finite* subset is in $\mathrm{Con}_{\mathbf{A}}$. The trick is that a finite subset of y must be a subset of one of the x_n, because the sequence of elements x_n is increasing. But all the terms of our given sequence are elements, and so, consistent; therefore, every finite subset of y is consistent.

The same argument also shows that the set y of data objects is closed under entailment, because $\vdash_{\mathbf{A}}$ is defined as a relation between finite (consistent) sets and data objects. It follows that since each x_n is a set closed under $\vdash_{\mathbf{A}}$, then so is y. In other words, y is indeed an element. Otherwise said, the domain $|\mathbf{A}|$ is closed under the formation of unions of increasing chains of elements, and the union is, of course, the sup

in the sense of the partial ordering. Again we have proved closure rather than assuming it, and the necessary properties of the sup follow from its definition as a union.

This last argument can be generalized—as is well known to mathematicians—to the case of *directed* families of elements. The word "directed," or better "upward-directed," means that every finite number of elements in the family is included in some further element of the family; chains always have this property. A good example of the use of directed sets of elements figures in the discussion of the *finite elements* of the domain.

As we have remarked several times, any consistent set of data objects *generates* an element by closing it up under the entailment relation; thus, in particular, any set $u \in \mathrm{Con}$ generates an element. Let us write

$$\overline{u} = \{X \in D_{\mathbf{A}} \mid u \vdash_{\mathbf{A}} X\}$$

for the *closure* of u under entailment. (This notation could be used for any consistent subset of $D_{\mathbf{A}}$, but the case of finitely generated elements is especially important.) Such a $\overline{u}$ is always an element of $|\mathbf{A}|$; the totality of such elements form, by definition, the *finite elements* of the domain. The notation $\overline{u}$ should of course be decorated with a subscript $\mathbf{A}$, but, as there is no good place to write it in, we leave it out.

We have for all elements x of the domain the basic formula:

$$x = \bigcup \{\overline{u} \mid u \in \mathrm{Con}_{\mathbf{A}} \text{ and } u \subseteq x\}.$$

This can be read intuitively as saying that every element of the domain is the *limit* of its *finite approximations*. And, having used the word "limit" so often, we ought now to say something about how to make the meaning of this word correct mathematically. Note that in the limit representation for x, the union is a directed one. (Why?)

Topological considerations. Geometrically speaking, a topological space is a collection of "points" which group themselves in various "neighborhoods" providing thereby a sense of "nearness." More specifically, a neighborhood of a point in a *metric space* consists of all those points within a certain positive "distance" from the given point; that is, nearness is limited, but it is not pushed to *zero*. The major reason for leaving some "breathing space" around the point comes out in defining continuity of functions.

A function f from one topological space to another is said to be *continuous* provided that, for every point x of the first space, and for every neighborhood in the second space around $f(x)$, it is possible to find—in the first space—a neighborhood around x with the following property. If the function is restricted to this neighborhood, then its values lie entirely in the given neighborhood around $f(x)$. In the metric case we can say that if we do not want the function to wander any great distance from $f(x)$, then there is a restricted distance around x giving a neighborhood over which the function values stay as close to $f(x)$ as specified. This keeps the function from jumping around wildly, since small variations in x lead to only small variations in $f(x)$.

The intuition about continuity is no doubt very clear in the more geometric examples, and geometric intuition can carry us quite far. But the spaces obtained from domain theory are not really geometric spaces, so we need to make some shifts in our metaphors. The geometric notion of a point usually implies that two points are perfectly distinguishable: if x and y are different, then they have disjoint neighborhoods. This is certainly true in the metric case, where, if two points are different, then they are at a positive distance apart. Early on in the study of topological spaces, however, it was found that not all spaces were metric, and weaker separation properties of pairs of distinct points were uncovered. One of the very weak versions of such a condition is called the "T_0-axiom." The best way to put it is that if two points have the same neighborhoods, then they are the same. The contrapositive statement sounds odd: if two points are distinct,

then there is a neighborhood that contains one but not the other. The oddity of this statement lies in the feeling that you cannot make up your mind over which is the better point.

In our domains there is already a notion of "betterness" which proves to be very closely related to the implicit neighborhood structure. The reason why our domains, as spaces of points, are not "geometric" in the familiar sense is that they contain partial elements. A geometric point, on the other hand, is "perfect" or totally determined; it cannot be made better than it already is. The metric in common spaces is measuring something other than betterness, for there are competing notions of approximation afoot here. Thus, we must keep our special goals in defining domains clearly in mind to avoid confusion.

Consider an information system $\mathbf{A}$. For each $u \in \mathrm{Con}_{\mathbf{A}}$, we define a corresponding neighborhood of $|\mathbf{A}|$ by the equation:

$$[u]_{\mathbf{A}} = \{x \in |\mathbf{A}| \mid u \subseteq x\}.$$

The neighborhoods of an element x are all those sets $[u]_{\mathbf{A}}$, where $u \subseteq x$. Note that this is the same as saying $\overline{u} \subseteq x$ or $\overline{u}$ approximates x. Indeed, the neighborhoods are in a one-one correspondence with the finite elements of $|\mathbf{A}|$. A neighborhood collects together all those elements sharing the same finite amount of information.

If both $u \subseteq x$ and $v \subseteq x$, then it is easy to see that the intersection of the two neighborhoods is again a neighborhood of x by virtue of the formula:

$$[u]_{\mathbf{A}} \cap [v]_{\mathbf{A}} = [u \cup v]_{\mathbf{A}}.$$

In case u and v are inconsistent with each other, then the intersection will be the empty set $\emptyset$. Because every element of our domain $|\mathbf{A}|$ is the union of the finite elements it contains, it is trivial to prove that two elements with exactly the same neighborhoods are the same. For these reasons, then, it follows that $|\mathbf{A}|$ is a T_0-topological space. The immediate reaction to this intelligence is: So what?

The answer to this scepticism will appear in the best light when we discuss in the next section the notion of function or mapping appropriate to our domains. The argument will be based on the extremely elementary form of the definition that characterizes the general continuous function together with the fact that the geometric intuition is suggestive of theorems to prove. In Section 6 we will find that the space of all continuous functions between two given domains is also a domain, a most useful result that is interesting topologically. But further interest for Domain Theory comes from the circumstance that there is a connection between geometry and domains. We cannot go into the full details here, but I can make some brief remarks.

Before continuing that discussion, though, it should be remarked that once the topology of the domain has been uncovered, then the unions of chains of elements (or directed sets of elements) are topological limits according to accepted general definitions. Thus, what we felt intuitively was a limiting process (the getting better and better up to the union) is in fact a limit formation in a precise mathematical sense. This helps convince us that we are on the right track.

Total elements as a space. In any domain it can be proved that any element x can be extended to a *total element* t, which is characterized by the property that it is a *maximal* element of the partial ordering. (Perhaps there are many such t, but there is always at least one with $x \subseteq t$.) Recall that the set of all total elements of $|\mathbf{A}|$ is denoted by $\mathrm{Tot}_{\mathbf{A}}$. Because the set $\mathrm{Tot}_{\mathbf{A}} \subseteq |\mathbf{A}|$, it is a topological space itself. Suppose s and t are two distinct total elements, then they must be inconsistent with each other—but we shall prove more. If every finite consistent $u \subseteq s$ also satisfied $u \subseteq t$, then $s \subseteq t$ would follow. But this is impossible, because s is maximal. Let, then, $u \in \mathrm{Con}_{\mathbf{A}}$ with $u \subseteq s$ be chosen so that $u \subseteq t$ fails. Now u must be inconsistent with t, since otherwise there would be an element containing them both. It follows that u must

be inconsistent with some $v \in \mathrm{Con}_{\mathbf{A}}$ with $v \subseteq t$. In this way we show that the neighborhoods $[u]_{\mathbf{A}}$ and $[v]_{\mathbf{A}}$ are disjoint.

This argument proves that $\mathrm{Tot}_{\mathbf{A}}$ is a *Hausdorff space* (or T_2-space). We cannot go further into the details here, but it is also a totally disconnected, compact Hausdorff space. (These spaces—well known from studies of Logic and the Theory of Boolean Algebras—are also zero-dimensional.) Assuming the countability of $\mathrm{Con}_{\mathbf{A}}$, which is not such a bold assumption, all such spaces can be conveniently embedded into the real line so as to preserve the topological structure. Perhaps this does not seem so surprising, but it shows that the topological nature of $\mathrm{Tot}_{\mathbf{A}}$, the uppermost level of the T_0 space $|\mathbf{A}|$, is indeed quite geometric. And it can also be shown that any arbitrary continuous function on $\mathrm{Tot}_{\mathbf{A}}$ into *any* topological space can be extended to a continuous function on $|\mathbf{A}|$, so the whole domain proves to be quite a "roomy" space with many good connections to more usual topological spaces.

A note on neighborhood structures. Topological spaces can be defined in several ways, and in general they do not carry a preferred neighborhood structure. (For example, there is no topological significance to the usual rational intervals we use to define neighborhoods for the real line: any similarly dense set of points would do in place of the rational numbers.) Domains, the way we have defined them, however, do have preferred neighborhoods. The set of finite elements of $|\mathbf{A}|$ can be defined topologically, and as we have seen they determine a convenient set of neighborhoods. (The reason for all this is the so-called zero-dimensional character of the domains. There is a higher-dimensional theory, but this leads to continuous lattices and can only be explained using the kind of presentation in Gierz, *et al.* [1980]. It is too long-winded a story for the present paper. The higher-dimensional domains do not have a preferred set of neighborhoods, however.)

Having realized this, it is a short step to giving an algebraic axiomatization of the neighborhood structure. Smyth [1975] contains a presentation in terms of the equivalent notion of

4.5 Approximable mappings between domains

Dependencies. Inside ApproximableMappingsBetweenDomains, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

Figure 51: Approximable mappings between domains.

Once a general notion of set or domain has been defined mathematically, the next major issue is: How are the different domains to be related one to another? The answer to this important question can many times be given by defining an appropriate concept of mapping between domains. The answer need not be unique; the same collection of domains may support more than one idea of function depending on the special aspects of the domains that need to be brought out. In the case of the kinds of domains being studied here, there are two principal answers, one of which is to be explained in this section.

In order to understand an appropriate notion of a mapping or a function between domains constructed from information systems, we have to refer back to the way in which elements are introduced. As we have seen in Section 3, an element is a consistent, closed set of data objects. To generate an element, one has to generate more and more of the finite consistent subsets of the element. Note that the separate data objects have to be grouped into these finite consistent sets, because the entailment relation may require a finite set

of arbitrary size on the left in making the necessary entailments for closure. It is this kind of passage from a finite set to its closure that is to be generalized in defining mappings.

Consider two domains. To map from one to another, some information about a possible element of the first is presented as input to the function f. Then as output the function f starts generating an element. If the input were u, a consistent set of the first domain, then part of the output in the second domain might be a consistent set v. We could say that there is an input/output relationship set up by f, and indicate by $u\ f\ v$ that this relation holds going from u in the first domain to v in the second. Of course to get the full effect of f, it is necessary to take all the v's related to a given u, because even a small finite amount of input may cause an infinite amount of output. But every element of a domain is just the sum total of its finite subsets (finite approximations), so it is sufficient to make the mapping relationship go between finite sets. Here is the formal definition with the exact conditions that the relation f must satisfy.

- Definition 5.1
- Definition 5.2
- Proposition 5.3
- Proposition 5.4
- Proposition 5.5
- Proposition 5.6

The proof is immediate, since we need only interpret the input/output relation $u\ (\mathrm{const}\ b)\ v$ as meaning $v \subseteq b$. We note that our notation is somewhat ambiguous since, for example, in 5.6(iii) we are using $\mathrm{const}\ b$ in two senses: once as a mapping from $\mathbf{A}$, and once as a mapping from $\mathbf{D}$. In fact, we should hang two subscripts on the thing to fix both the source and the target of the mapping. This is too painful, however, and we generally rely on context to make the meaning clear. (Formal rules of type checking can be given, so on a computer-based system all the necessary subscripts could be put back in. Thus, the kind of ambiguity we are dealing with here is not very serious.)

4.6 Products and sums of domains

Dependencies. Inside ProductsAndSumsOfDomains, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

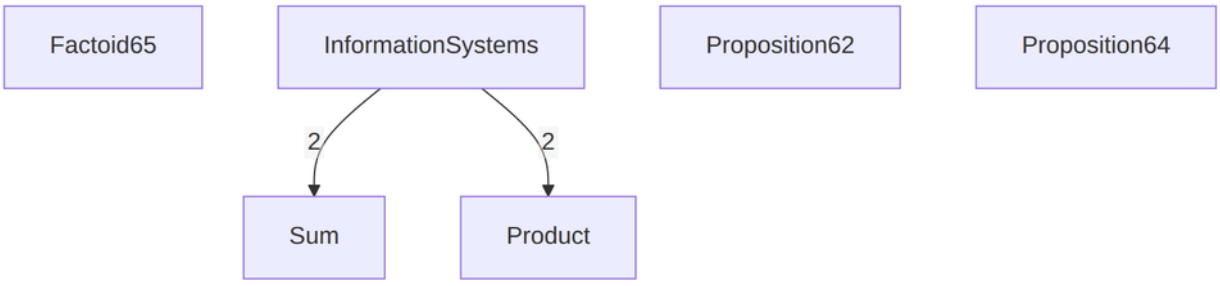

Figure 52: Products and sums of domains.

In the category of sets, the product (the cartesian product) of two sets is by definition just the set of ordered pairs of elements. We could use the same definition in the category of domains—provided we worked in terms of the elements of the domains. The disadvantage is that the determination of the product domain from data objects is lost, or at least pushed into the background. We shall therefore give a construction of products directly in terms of the given data objects, and then show how to prove that the product is just the one expected when we look at the elements.

The idea for the definition is a simple one. Think of two domains $\mathbf{A}$ and $\mathbf{B}$. A data object $X \in D_{\mathbf{A}}$ can be giving information about a possible element $x \in |\mathbf{A}|$, and a data object $Y \in D_{\mathbf{B}}$ can be giving information about a possible element $y \in |\mathbf{B}|$. How do we wish to give information about the pair (x, y)? The first piece of advice is not to say all that is known all at once. For example, if pressed, we can say we know X about the first coordinate of the pair; only later, if really pressed, we can say we also know Y about the second coordinate. The point is that data objects provide only partial information, and it does not matter if it takes several of them to give fairly complete information about the whole element. This attitude motivates, then, the particular form of our official definition.

- Definition 6.1
- Proposition 6.2
- Definition 6.3
- Proposition 6.4

It can also be shown that Propositions 6.2 and 6.4 uniquely characterize the domains $\mathbf{A} \times \mathbf{B}$ and $\mathbf{A} + \mathbf{B}$ up to isomorphism, and they give us the existence of additional mappings that are needed to show that product and sum are functors on the category of domains. We can also show from these results that the domain

$$\mathbf{BOOL} = \mathbf{1} + \mathbf{1}$$

has two elements true and false, such that any mapping on $\mathbf{BOOL}$ is uniquely determined by its action on true, false and $\perp_{\mathbf{BOOL}}$, and the values on the first two elements may be arbitrarily chosen.

4.7 The function space as a domain

Dependencies. Inside FunctionSpaceAsADomain, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

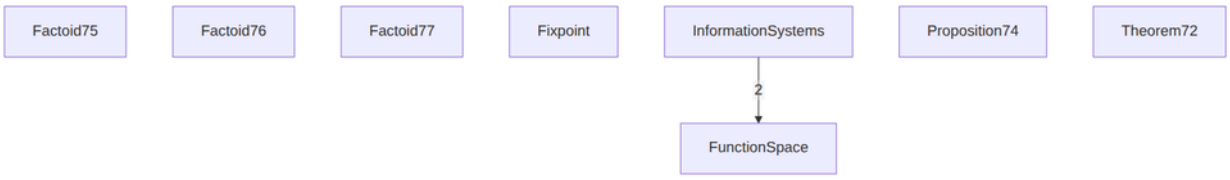

Figure 53: The function space as a domain.

Functions or mappings between domains are of basic importance for our theory, since it is through them that we most easily transform data and relate the structures into which the elements defined by the data objects enter. There are many possible functions, and large groups of them can be treated in a uniform manner. For instance, if the source and target domains match properly, any pair of functions can be composed—composition is an operation on functions of general significance. Now, if in the theory we could combine functions into domains themselves, then an operation like composition might become a mapping of the theory. Indeed, this is exactly what happens: suitably construed, composition is an approximable mapping of two arguments. Of course, for each configuration of linked source and target domains, there is a separate composition operation.

In order to make approximable mappings elements of a suitable domain, we have to discover first what their appropriate data objects are. In Section 5 this was hinted at already. To determine an approximable mapping $f : \mathbf{A} \to \mathbf{B}$, we have to say which pairs (u, v) with $u \in D_{\mathbf{A}}$ and $v \in D_{\mathbf{B}}$ stand in the mapping relation $u\ f\ v$. One such pair gives a certain (finite) amount of information about the possible functions that contain it, and an approximable mapping is completely determined by such pairs. Therefore, if there are appropriate notions of consistency and entailment for these pairs, we will be able to form a domain having functions as elements. Let us try out a formal definition first, and then look to an explanation of how it works.

4.8 Some domain equations

Dependencies. Inside SomeDomainEquations, each box is one subfolder, or one Lean file sitting directly in the folder. A box named as another folder in this chapter is that whole folder. A box named as another chapter is that whole chapter. The arrowhead points at the file or folder that imports, and the number is how many direct imports.

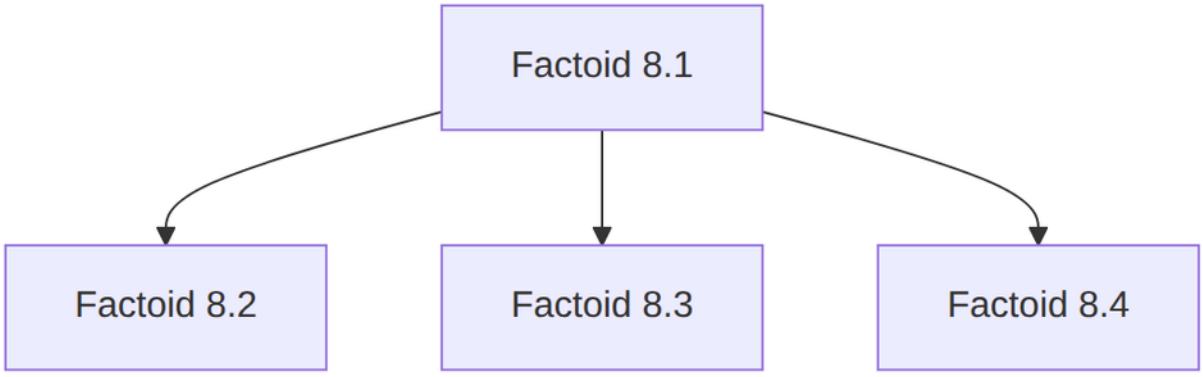

Figure 54: Some domain equations.

Having outlined the theory of several domain constructs, the final topic for this paper will be the discussion of the *iteration* of these constructs in giving *recursive*, rather than direct definitions of domains. These recursively defined systems have often been called "reflexive," because the domains generally contain copies of themselves as a part of their very structure. The way that this self-containment takes place is best expressed by the so-called *domain equations*, which are really isomorphisms that relate the domain as a whole to a combination of domains—usually with the main domain as a component. This description is rough, since recursion equations for domains can be as complex as recursion equations for functions. We will not enter into a full theory of domain equations now but will just review some preliminary examples to illustrate how the new presentation makes the constructions more explicit.

4.8.1 Factoid 8.1

A domain of trees or S-expressions. This is everyone's favorite example. And a very nice example it is, but we should not think that it contains all the meat of the theory of domain equations. Even if we generalize the kinds of equations to contain all iterations of the domain constructs $+$ and $\times$, the full power of the method has not been exploited. We will try to make this clear in the further examples.

Let a domain (information system) $\mathbf{A}$ be given. What we want to construct is a domain $\mathbf{T}$ of "trees" built up from elements of $\mathbf{A}$ as "atoms". For simplicity we consider unlabelled binary trees here, but more complex trees are easy to accommodate. The domain equation we want to "solve" is this one:

$$\mathbf{T} \cong \mathbf{A} + (\mathbf{T} \times \mathbf{T}).$$

If such a domain exists, then we can say that (up to isomorphism) the elements of the domain $\mathbf{T}$ are either bottom, or elements of the given domain $\mathbf{A}$, or pairs of elements from the domain $\mathbf{T}$ itself. And these are the only kinds of elements that $\mathbf{T}$ has.

To prove that such a domain exists it is only necessary to ask what information has to be given about a prospective element. The answer may involve us in a regress, but the running backwards need not be infinite—at least for the finite elements. As we shall see, the infinite elements of $\mathbf{T}$ can be self-replicating; but, to define a domain fully, all we have to do is to build up the finite elements out of the data objects in a systematic way. Fortunately, in order to satisfy the above equation, the required closure conditions on data objects are simple to achieve.

In the first place, we need copies of all the data objects of $\mathbf{A}$ to put into the sum. The easy way to do this is to take an object Δ not in $D_{\mathbf{A}}$, and to let, by definition,

$$\Delta_{\mathbf{T}} = (\Delta, \Delta).$$

That gives us one member of $D_{\mathbf{T}}$, the one we always have to have in any case. The copy of an $X \in D_{\mathbf{A}}$ is just going to be (X, Δ). The other members of $D_{\mathbf{T}}$ will be of the form (Δ, U), where U gives us information about the other kind of elements of $\mathbf{T}$. The point is that $\mathbf{T}$ has to be a sum, and we are using just the scheme of Definition 6.3 to set this up.

Next we have to think what kind of information the U above should contain. Because we want a product, we refer back to Definition 6.1 and imagine we have already defined $D_{\mathbf{T}}$. What 6.1(i) suggests is that we throw in a bunch of other data objects into $D_{\mathbf{T}}$. The only point that needs care is that the data objects for the product must be copied into the overall sum. With this in mind, the following clauses give us the inductive definition of $D_{\mathbf{T}}$:

(1) $\Delta_{\mathbf{T}} \in D_{\mathbf{T}}$;

(2) $(X, \Delta) \in D_{\mathbf{T}}$ whenever $X \in D_{\mathbf{A}}$; and

(3) $(\Delta, (Y, \Delta_{\mathbf{T}})) \in D_{\mathbf{T}}$, and $(\Delta, (\Delta_{\mathbf{T}}, Z)) \in D_{\mathbf{T}}$ whenever $Y, Z \in D_{\mathbf{T}}$.

Of course, when we say "inductive definition," we mean that $D_{\mathbf{T}}$ is the least class satisfying (1)–(3). By standard arguments it can be shown that $D_{\mathbf{T}}$ satisfies this set-theoretical equation:

$$D_{\mathbf{T}} = \{\Delta_{\mathbf{T}}\} \cup \{(X, \Delta) \mid X \in D_{\mathbf{A}}\} \cup \{(\Delta, (Y, \Delta_{\mathbf{T}})) \mid Y \in D_{\mathbf{T}}\} \cup \{(\Delta, (\Delta_{\mathbf{T}}, Z)) \mid Z \in D_{\mathbf{T}}\}.$$

In fact, with some very mild assumptions about ordered pairs in set theory, $D_{\mathbf{T}}$ is the only solution to the above equation.

Defining the data objects is but part of the story: the same data objects can enter into quite different information systems. Data objects are just "tokens" and are only given "meaning" when $\mathrm{Con}_{\mathbf{T}}$ and $\vdash_{\mathbf{T}}$ are defined. Let us consider the problem of consistency first. We already understand the notion as it applies to sum and product systems, so we must merely copy over the parts of the previous definitions in the right position for the definition of $\mathrm{Con}_{\mathbf{T}}$. There are two forms we could give this definition; perhaps the best is the inductive one. We have:

(4) $\emptyset \in \mathrm{Con}_{\mathbf{T}}$;

(5) $u \cup \{\Delta_{\mathbf{T}}\} \in \mathrm{Con}_{\mathbf{T}}$ whenever $u \in \mathrm{Con}_{\mathbf{T}}$;

(6) $\{(X, \Delta) \mid X \in w\} \in \mathrm{Con}_{\mathbf{T}}$ whenever $w \in \mathrm{Con}_{\mathbf{A}}$;

(7) $\{(\Delta, (Y, \Delta_{\mathbf{T}})) \mid Y \in u\} \cup \{(\Delta, (\Delta_{\mathbf{T}}, Z)) \mid Z \in v\} \in \mathrm{Con}_{\mathbf{T}}$ whenever $u, v \in \mathrm{Con}_{\mathbf{T}}$.

Conditions (4)–(7) certainly make the inductive character of $\mathrm{Con}_{\mathbf{T}}$ clear—again, let us emphasize, the set being specified is the least such. Also clear from the definition is the fact that a consistent set of $\mathbf{T}$—aside from containing $\Delta_{\mathbf{T}}$—is either a copy of a consistent set of $\mathbf{A}$ or a copy of a consistent set of $\mathbf{T} \times \mathbf{T}$. We could thus state a set-theoretical equation for $\mathrm{Con}_{\mathbf{T}}$ similar to the one for $D_{\mathbf{T}}$.

It remains to define entailment for $\mathbf{T}$. Here are the inductive clauses which are pretty much forced on us by our objective of solving the domain equation:

(8) $u \vdash_{\mathbf{T}} \Delta_{\mathbf{T}}$ always;

(9) $u \cup \{\Delta_{\mathbf{T}}\} \vdash_{\mathbf{T}} Y$ whenever $u \vdash_{\mathbf{T}} Y$;

(10) $\{(X, \Delta) \mid X \in w\} \vdash_{\mathbf{T}} (W, \Delta)$ whenever $w \vdash_{\mathbf{A}} W$;

(11) $\{(\Delta, (Y, \Delta_{\mathbf{T}})) \mid Y \in u\} \cup \{(\Delta, (\Delta_{\mathbf{T}}, Z)) \mid Z \in v\} \vdash_{\mathbf{T}} (\Delta, (X, \Delta_{\mathbf{T}}))$ whenever $u \vdash_{\mathbf{T}} X$ and $v \in \mathrm{Con}_{\mathbf{T}}$; and

(12) $\{(\Delta, (Y, \Delta_{\mathbf{T}})) \mid Y \in u\} \cup \{(\Delta, (\Delta_{\mathbf{T}}, Z)) \mid Z \in v\} \vdash_{\mathbf{T}} (\Delta, (\Delta_{\mathbf{T}}, X))$ whenever $v \vdash_{\mathbf{T}} X$ and $u \in \mathrm{Con}_{\mathbf{T}}$.

Inductive definitions engender inductive proofs. It now has to be checked that consistency and entailment for $\mathbf{T}$ satisfy the axioms of 2.1. The steps needed for this check are mechanical. (The proof may be aided by noting that the cases in (4)–(7) and in (8)–(12) are disjoint—except for a trivial overlap between (8) and (9). The cases get invoked typically by asking, when confronted with an entailment to prove, for the nature of the data object on the right of the turnstile.)

Having defined and verified that $\mathbf{T}$ is an information system, the validity of the domain equation for $\mathbf{T}$ is secured by forming the right-hand side and noting that $\mathbf{T}$ is *identical* to $\mathbf{A} + (\mathbf{T} \times \mathbf{T})$. The reason is that we carefully chose the notation to match the official definitions of sums and products. (In general, in solving domain equations some transformation might have to take place to "re-format" data objects if things are not set up to be literally the same.)

It should be remarked that the sense can be made precise in which $\mathbf{T}$ is the *least* solution of the given domain equation. (It is an initial algebra in a suitable category of algebras and algebra homomorphisms.) It is pretty obvious that it is minimal in some sense, because we put into it only what was strictly required by the problem and nothing more.

It is also fairly obvious that there are *many* solutions to this domain equation. A non-constructive way to obtain non-minimal solutions is to interpret the whole construction of $\mathbf{T}$ in a non-standard model of set theory. Though, in the definition of $D_{\mathbf{T}}$, it looks like we are only working with very finite objects, everything we did could be made abstract and could be carried out in some funny universe. The result would be a system of "finite" data objects having all the right formal properties but containing things not in the standard minimal system. We would then take the notions of consistency and entailment that also exist in the funny universe and restrict them to sets of data objects that are actually finite in the standard sense. It can be seen from the formal properties of the construction that the resulting notions satisfy our axioms for an information system and that the domain equation holds—BUT the system would have many different elements beyond what we put into the original $\mathbf{T}$. To make this construction work, by the way, we would have to force $\mathbf{A}$ to be absolute in the model: if it is actually finite (say, $\mathbf{A} = \mathbf{BOOL}$), then there is no problem. (Constructive methods for introducing "nonstandard" data objects can also be given.)

Finally, we must remark on why we called $\mathbf{T}$ a domain of S-expressions. The answer becomes clear when we structure $\mathbf{T}$ as an algebra. First, there is an approximable mapping

$$\mathrm{atom} : \mathbf{A} \to \mathbf{T},$$

which injects $\mathbf{A}$ into $\mathbf{T}$ making the elements of $\mathbf{A}$ "atoms" of $\mathbf{T}$. Then there is a truth-valued predicate on $\mathbf{T}$ which decides whether an element is an atom:

$$\mathrm{isatom} : \mathbf{T} \to \mathbf{BOOL}.$$

Finally, since $\mathbf{T} \times \mathbf{T}$ is a part of $\mathbf{T}$, we can redefine the paring functions so that:

$$\text{pair} : \mathbf{T} \times \mathbf{T} \to \mathbf{T}, \quad \text{fst} : \mathbf{T} \to \mathbf{T}, \quad \text{and snd} : \mathbf{T} \to \mathbf{T}.$$

In LISP terminology, these operations are the same as the familiar cons, car, and cdr. This makes $\mathbf{T}$ into an algebra where, starting from atoms, elements—expressions—can be built up by iterated pairing.

But why is our system different from the usual way of regarding S-expressions? The answer is that by including partial expressions (those involving $\Delta_{\mathbf{T}}$) and by completing the domain with limits, *infinite* expressions are introduced. For instance, if $a \in |\mathbf{T}|$, then we can solve the fixed-point equation:

$$x = \text{pair}(\text{atom}(a), x),$$

which is an infinite list of a's. This is but one example; the possibilities have been discussed in many papers too numerous to mention here.

As is common to remark, S-expressions can also be thought of as trees: the parse tree that gives the grammatical form of the expression. What we have added to the idea of a tree is the possibility of having infinite trees, and having all these trees as elements of a domain. ■
