3.6.12 Exercise 5.11 — stack combinators

For any domain $\mathcal{D}$ we may regard $\mathcal{D}^\infty$ as consisting of (bottomless) *stacks* of elements of $\mathcal{D}$. With this image in mind, define appropriate combinators with the obvious meanings:

$$\mathrm{head} : \mathcal{D}^\infty \to \mathcal{D}; \quad \mathrm{tail} : \mathcal{D}^\infty \to \mathcal{D}^\infty; \quad \mathrm{push} : \mathcal{D} \times \mathcal{D}^\infty \to \mathcal{D}^\infty.$$

Using the fixed-point theorem argue that there is a combinator

$$\mathrm{diag} : \mathcal{D} \to \mathcal{D}^\infty$$

where for all $x \in |\mathcal{D}|$ we have

$$\mathrm{diag}(x) = \langle x \rangle_{n=0}^{\infty}.$$

(Hint: Try a recursive definition, say

$$\mathrm{diag}(x) = \mathrm{push}(x, \mathrm{diag}(x)),$$

but be sure to prove *all* terms of $\mathrm{diag}(x)$ equal x.) Also introduce by an appropriate recursion a combinator

$$\mathrm{map} : (D \to D)^\infty \times D \to D^\infty$$

where for elements of the suitable types:

$$\mathrm{map}(\langle f_n \rangle_{n=0}^{\infty}, x) = \langle f_n(x) \rangle_{n=0}^{\infty}.$$

3.6.13 Exercise 5.12 — while combinator

On any domain D introduce (as a least fixed point) a combinator

$$\text{while} : (D \to T) \times (D \to D) \to (D \to D)$$

by the recursion

$$\text{while}(p, f)(x) = \text{cond}(p(x), \text{while}(p, f)(f(x)), x).$$

Prove that

$$\text{while}(p, \text{while}(p, f)) = \text{while}(p, f).$$

Show how while could have been used to obtain the least number operator mentioned in the proof of 5.6. Generalize the idea to define a combinator

$$\text{find} : D^\infty \times (D \to T) \to D$$

with the meaning "find the first term of the sequence (if any) which satisfies the given precicate."

3.6.14 Exercise 5.13 — pairing function on numbers

Prove the existence of a one-one function $\mathrm{num} : \mathbf{N} \times \mathbf{N} \to \mathbf{N}$ such that

$$\mathrm{num}(0,0) = 0;$$

$$\mathrm{num}(n, m+1) = \mathrm{num}(n+1, m) + 1;$$

$$\mathrm{num}(n+1, 0) = \mathrm{num}(0, n) + 1.$$

Draw a picture (i.e. an infinite matrix) for the function and find a closed form for its values, if possible. Use the function to prove the isomorphism of the domains

$$P\mathbf{N},\ P(\mathbf{N} \times \mathbf{N}),\ P\mathbf{N} \times P\mathbf{N}.$$

3.6.16 Exercise 5.14 — functions as graphs

Show that there are approximable mappings

$$\mathrm{graph} : (P\mathbf{N} \to P\mathbf{N}) \to P\mathbf{N} \quad \text{and} \quad \mathrm{fun} : P\mathbf{N} \to (P\mathbf{N} \to P\mathbf{N}),$$

where we have

$$\mathrm{fun} \circ \mathrm{graph} = \lambda f.\, f, \quad \text{and} \quad \mathrm{graph} \circ \mathrm{fun} \supseteq \lambda x.\, x.$$

(Hint: Using the notation

$$[n_0, n_1, \ldots, n_k] = \mathrm{num}(n_0, [n_1, \ldots, n_k])$$

two such combinators can be given by formulae

$$\mathrm{fun}(u)(x) = \{m \mid \exists n_0, \ldots, n_{k-1} \in x.\, [n_0 + 1, \ldots, n_{k-1} + 1, 0, m] \in u\}$$

$$\mathrm{graph}(f) = \{[n_0 + 1, \ldots, n_{k-1} + 1, 0, m] \mid m \in f(\{n_0, \ldots, n_{k-1}\})\}$$

where k is variable — meaning all finite sequences are to be considered.)

3.6.17 Exercise 5.15 — star of a word

(For algebraists.) We can regard $\langle \{0,1\}^*, \Lambda, \cdot \rangle$ as the free semigroup on two generators 0 and 1. The powerset $P\{0,1\}^*$ is taken as a domain as in Exercise 4.17. For "words" $e \in \{0,1\}^*$ define

$$e^* = \{\Lambda, e, e^2, e^3, \ldots, e^n, \ldots\}.$$

Show that the least fixed point of

$$z = \{e\} \cdot z \cup \{e'\}$$

in $P\{0,1\}^*$ is $z = e^* \cdot \{e'\}$.

Show further (as suggested by David Park) that the least solution of

$$x = a \cdot x \cup b \cdot y \cup c,$$
$$y = b \cdot x \cup a \cdot y \cup d$$

has

$$x = (a \cup b \cdot a^* \cdot b)^* \cdot (c \cup b \cdot a^* \cdot d),$$

where the $\{\cdot\}$ has been dropped off $\{a\}$, $\{b\}$ etc., and where the *-notation has been extended to the whole domain, so that $z^* = \Lambda \cup z^* \cdot z$.

(Hint: Apply 5.3.)

3.6.18 Exercise 5.16 — negation of sequences

Return to the discussion of Example 4.4 and the construction of the domain of finite and infinite binary sequences. Give a fixed-point definition of $\mathrm{neg} : C \to C$, where

$$\mathrm{neg}(0x) = 1\,\mathrm{neg}(x); \qquad \mathrm{neg}(1x) = 0\,\mathrm{neg}(x).$$

Prove that $\mathrm{neg}(\mathrm{neg}(x)) = x$ for all $x \in |C|$. Also define $\mathrm{merge} : C \times C \to C$, where for $\epsilon, \delta \in \{0, 1\}$ we have:

$$\mathrm{merge}(\epsilon x, \delta y) = \epsilon\,\delta\,\mathrm{merge}(x, y).$$

(Note: There may be a little trouble with $\mathrm{merge}(x, y)$ when x is finite and total and y is infinite—you have to decide what you want in e.g. $\mathrm{merge}(\Lambda, y)$.) Prove that

$$\mathrm{merge}(x, x) = d(x),$$

in the notation of 4.4. Consider also the infinite non-periodic sequence

$$t = 0\,\mathrm{merge}(\mathrm{neg}(t), \mathrm{tail}(t)).$$

Prove that the nth digit of t is the sum mod 2 of the digits of the number n written in the binary scale (a suggestion of J. Lambek). Show also that $t \neq u\,a\,a\,a\,v$ where a is any finite sequence $\neq \Lambda$, and where u is finite.

3.7 Domain equations

Dependency diagram. Each box is one item. The arrowhead is on the item that imports. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it is not shown. Blue is a definition, green a proposition or lemma, amber an example, red a theorem, and indigo an exercise.

3.7.1 Introduction

LECTURE VI INTRODUCTION TO DOMAIN EQUATIONS

The major reason for introducing the theory of domains is to have a notion of *computability* incorporating both finite and infinite elements. In our many examples already explored we have seen how functions (functionals, operators, combinators) can be defined on domains; owing to the property of *approximability (continuity)* of these functions, we have also seen how they can be "calculated" by finite approximation. In this lecture further examples of domains will be constructed – especially domains having infinite elements, which can be introduced in a variety of ways giving rise to interesting structural possibilities. The next

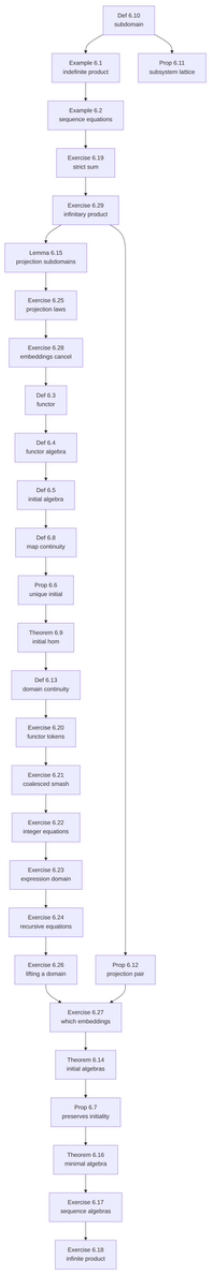

Figure 35: Domain equations.

lecture then treats a precise notion of *computability* appropriate to these domains; while the last lecture opens up new methods of domain construction.

3.7.2 Example 6.1 — indefinite product

EXAMPLE 6.1. Let D be fixed as a given domain. We are now familiar with a useful construct like $D \times D$ whose elements are ordered pairs $\langle x, y\rangle$ of elements x, y of D. The question is: can this construct be iterated? The answer is obviously yes, since $D \times (D \times D)$ and $(D \times D) \times (D \times D)$ and so on can be formed with elements $\langle x, \langle y, z\rangle\rangle$ and $\langle\langle u, v\rangle, \langle x, y\rangle\rangle$ and the like. But the real question is: can the construct be iterated *indefinitely*? AND can the results be collected together into a *single* domain? The answer is yes, but it requires a bit of work to get it right. The method to be introduced will be open to many variations, so more than one answer is possible, giving non-isomorphic domains.

In order to collect all the iterates into one large domain we give ourselves first a very big domain inside of which the desired family of neighbourhoods will be found. There are many ways to make this choice, and we are fixing on one that will keep the notation simple. We have often used binary sequences for examples and constructions, but for this example let us use

ternary sequences. Let $\Sigma = \{0, 1, 2\}$ and let Σ^* be all finite sequences from this three-letter alphabet. We will select subsets of Σ^* for our neighbourhoods. As Σ^* is countably infinite, it is without much loss of generality to assume that $\mathcal{D}$ is a neighbourhood system over Δ, where we take $\Delta \subseteq \Sigma^*$. Also without loss of generality we can assume $\emptyset \notin \mathcal{D}$. (Why?)

We wish to find another set $\Gamma \subseteq \Sigma^*$ to be the set of tokens for the new domain. After we find it, we will still have to say just which $X \subseteq \Gamma$ are appropriate for the structure we want.

The totality $\{X \mid X \subseteq \Sigma^*\}$ is, as a powerset, isomorphic to the set of elements of a domain: a point we have remarked several times. So, by the Fixed-Point Theorem we know there is a set $\Gamma \subseteq \Sigma^*$ where

$$\Gamma = 0\Delta \cup 1\Gamma \cup 2\Gamma.$$

In fact $\Gamma = \{1, 2\}^*0\Delta$, because we can say:

$$\{1, 2\}^* = \{\Lambda\} \cup 1\{1, 2\}^* \cup 2\{1, 2\}^*.$$

The domain we are looking for will be found as a domain $\mathcal{D}^\S$ over Γ. The reason for splitting Γ up, as shown in the equation above, is to ensure that if $X, Y \in \mathcal{D}^\S$ are two neighbourhoods in the system $\mathcal{D}^\S$, then $1X \cup 2Y$ has a chance of being also in $\mathcal{D}^\S$ because

$$1X \cup 2Y \subseteq \Gamma.$$

This will make $\mathcal{D}^\S \times \mathcal{D}^\S$ isomorphic to a part of $\mathcal{D}^\S$. If we make $\mathcal{D}$ also isomorphic to a part of $\mathcal{D}^\S$, then all the iterated products will be contained in $\mathcal{D}^\S$.

What is a neighbourhood system? Just a set of sets. But $\mathcal{PP}\Sigma^*$ is a domain (as a power set) and because $\Gamma \subseteq \Sigma^*$, we find

$$\mathcal{D}^\S \in \mathcal{PP}\Sigma^*$$

as an element. But elements of domains can often be defined by fixed-point equations. Indeed we will introduce $\mathcal{D}^\S$ this way:

$$\mathcal{D}^\S = \{\Gamma\} \cup \{0X \mid X \in \mathcal{D}\} \cup \{1X \cup 2Y \mid X, Y \in \mathcal{D}^\S\}.$$

The reader should stop to think why $\mathcal{D}^\S$ can be immediately seen to exist by writing such an equation. Of course another way to describe $\mathcal{D}^\S$ is to say it is the least family of sets containing (i) the set Γ, (ii) the sets $0X$ for X in the given system $\mathcal{D}$, and (iii) sets $1X \cup 2Y$ whenever it already contains X and Y (closure under a set-forming operation). By saying "least" we mean (iv) nothing else belongs to $\mathcal{D}^\S$ except as allowed by (i)–(iii); this makes the truth of the equation for $\mathcal{D}^\S$ clear. So $\mathcal{D}^\S$ exists as a family of sets, but what good is it?

By our construction of Γ, all the sets we put into $\mathcal{D}^\S$ are subsets of Γ (why?); so $\mathcal{D}^\S$ has a chance of being a system over Γ if we can check the closure under intersection. So suppose $Z \subseteq X \cap Y$ where $Z, X, Y \in \mathcal{D}^\S$; we want to show $X \cap Y \in \mathcal{D}^\S$. We argue by induction on the number of steps required to put X and Y into $\mathcal{D}^\S$ by (i)–(iii). There are several cases.

If $X = \Gamma$ or $Y = \Gamma$, there is nothing to prove, because both sets are subsets of Γ. We note that $\emptyset \notin \mathcal{D}^\S$, because (i)–(iii) cannot introduce $\emptyset$ as a member of $\mathcal{D}^\S$. So, if $X = 0A$ for $A \in \mathcal{D}$, then Y must have this form also (if it is not Γ), because

$$0A \cap (1B \cup 2C) = \emptyset.$$

(That is, if Y had the form (iii), then $Z = \emptyset$ would be a consequence, which is impossible.) Thus, if $X = 0A$ for $A \in \mathcal{D}$, then $Y = 0B$ for some $B \in \mathcal{D}$. But by the same reasoning $Z = 0C$ for some $C \in \mathcal{D}$ also. But the relationship $0C \subseteq 0A \cap 0B$ is equivalent to $C \subseteq A \cap B$. We see, therefore, that $A \cap B \in \mathcal{D}$, and so

$$X \cap Y = 0A \cap 0B = 0(A \cap B)$$

must belong to $\mathcal{D}^\S$.

The final case has X, Y, Z all of the form (iii):

$$X = 1A_1 \cup 2A_2,$$

$$Y = 1B_1 \cup 2B_2, \text{ and}$$

$$Z = 1C_1 \cup 2C_2.$$

We can think of the A_i and B_i put into $\mathcal{D}^\S$ earlier and the intersection result as being already established for them. But the relationship $Z \subseteq X \cap Y$ is equivalent to $C_i \subseteq A_i \cap B_i$ for $i = 1, 2$. Therefore $A_i \cap B_i \in \mathcal{D}^\S$, and so does

$$X \cap Y = (1A_1 \cup 2A_2) \cap (1B_1 \cup 2B_2) = 1(A_1 \cap B_1) \cup 2(A_2 \cap B_2).$$

We have now seen that $D^\S$ is a neighbourhood system, but why was it constructed that way? The reason is simply this isomorphism (or domain equation):

$$D^\S \cong D + (D^\S \times D^\S),$$

as can be seen by reference to the equation for $D^\S$ and the definitions of $+$ and $\times$. What are the elements of $D^\S$? There is always

$$\perp = \{\Gamma\}.$$

Next if $x \in |D|$ we define

$$x^{\S} = \{\Gamma\} \cup \{0X \mid X \in x\}.$$

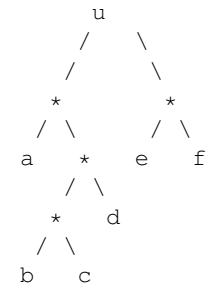
That gives an isomorphic injection

$$\lambda x.\, x^{\S} : D \to D^{\S}.$$

Then for $x, y \in |D^{\S}|$ we can define

$$\langle x, y\rangle = \{\Gamma\} \cup \{1X \cup 2Y \mid X \in x \text{ and } Y \in y\}.$$

We have another isomorphic injection



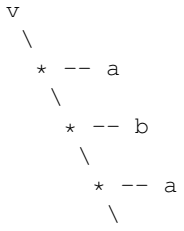
$$\lambda x, y.\, \langle x, y\rangle : D^{\S} \times D^{\S} \to D^{\S}.$$

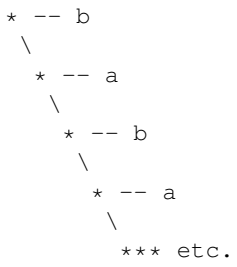
Indeed by looking at the neighbourhood definition of $D^{\S}$ we conclude that the *finite* elements of $D^{\S}$ are exactly those that are either of the form (i) $\perp$, or (ii) $a^{\S}$, where a is finite in $|D|$, or (iii) $\langle a, b\rangle$, where a and b are previously obtained finite elements of $|D^{\S}|$.

Suppose $a, \ldots, f$ are finite in $|D|$. We can picture the element

$$u = \langle\langle a^{\S}, \langle\langle b^{\S}, c^{\S}\rangle, d^{\S}\rangle\rangle, \langle e^{\S}, f^{\S}\rangle\rangle$$

in $|D^{\S}|$ as a tree:





Note that the tree has binary branching with the elements of $|D|$ at the ends of the branches. Any such tree could be given a notation as an element of $|D^{\S}|$. The finite elements of $|D^{\S}|$ correspond exactly to such finite trees.

What of the infinite elements of $|D^{\S}|$? Are there infinite trees? Let $a, b \in |D^{\S}|$ be any elements of $|D^{\S}|$. Since pairing is an approximable mapping, we can solve the fixed-point equation

$$v = \langle a, \langle b, v\rangle\rangle.$$

In pictures we can diagram v roughly as:

The word is "roughly" here, since if a or b were not in the $|D|$ part of $|D^{\S}|$, then in the diagram the letters "a" and "b" should be replaced by the corresponding tree diagrams for a and b.

Suppose that a and b are finite. Then we can easily see that the infinite tree v is the limit of the following sequence of finite trees:

$$v_0 = \bot,$$

$$v_{n+1} = \langle a, \langle b, v_n \rangle \rangle,$$

and

$$v = \bigsqcup_{n=0}^{\infty} v_n.$$

The reader should think how to explain from tree diagrams the approximation relation $v_n \sqsubseteq v$ and more general such relationships.

We could call $D^{\S}$ a tree algebra over D. There may be others. A general one is a structure of the form

$$\langle E, \text{in}, \text{pair} \rangle,$$

where

$$\text{in} : D \to E, \text{ and}$$

$$\text{pair} : E \times E \to E.$$

The algebra

$$\langle D^{\S}, \lambda x.\, x^{\S}, \lambda x, y.\, \langle x, y \rangle \rangle,$$

however, is a very special one: it is "minimal" among all tree algebras over D in a sense we shall have to make precise.

To do this think of how E and $D^{\S}$ can differ. In view of the isomorphism that $D^{\S}$ satisfies, the injection of D and the pairing are one-one, so no "information" is lost by these mappings. The same may not at all be true of E, but it is reasonable to think that at least we can define an approximable mapping $g : D^{\S} \to E$ where

$$(1) \quad g(\bot) = \bot_E,$$

$$(2) \quad g(x^{\S}) = \text{in}(x), \text{ for } x \in |D|, \text{ and}$$

$$(3) \quad g(\langle x, y\rangle) = \text{pair}(g(x), g(y)), \text{ for } x, y \in |D^{\S}|.$$

By what we said earlier, g will be uniquely determined by (1)–(3), because these equations tell us exactly how to calculate g on all finite elements of $|D^{\S}|$. An approximable mapping is always determined by its action on the finite elements. But why does g exist?

It would not be too hard to give an inductive construction of g as a neighbourhood relation, but a fixed-point equation is easier to write down for the same purpose. We need, though, to have the inverse ("predecessor") functions:

$$\text{out} : D^{\S} \to D$$

$$\text{proj}_i : D^{\S} \to D^{\S}, \text{ for } i = 0, 1,$$

where

$$\text{out}(x^{\S}) = x,$$

$$\text{proj}_0(\langle x, y\rangle) = x, \text{ and}$$

$$\text{proj}_1(\langle x, y\rangle) = y.$$

We also need

$$\text{atom} : D^{\S} \to T,$$

where

$$\text{atom}(x^{\S}) = \text{true}, \text{ and}$$

$$\text{atom}(\langle x, y\rangle) = \text{false}.$$

We can then write

$$g(x) = \text{cond}\big(\text{atom}(x), \text{in}(\text{out}(x)), \text{pair}(g(\text{proj}_0(x)), g(\text{proj}_1(x)))\big).$$

This g exists by fixed-point theory, and it satisfies (1)–(3) by what we know about the structure of $|D^{\S}|$. As we said, g is unique because the values on finite elements are fixed.

In algebraic language g is a *homomorphism* of tree algebras; and $D^{\S}$ is called an *initial algebra*, because for any tree algebra E there is a unique homomorphism $g : D^{\S} \to E$. We note at once that any two initial algebras are isomorphic. For if D^* were another, there would exist homomorphisms in both directions between $D^{\S}$ and D^*. But the compositions of homomorphisms are again homomorphisms, and in the case of $D^{\S}$ if we go from $D^{\S}$ to D^* and back to $D^{\S}$, the result must be the identity. The reason is that the identity can be the only homomorphism of an initial algebra into itself. We thus have a precise meaning of the minimal character of $D^{\S}$. But note it still took a construction to show that the domain $D^{\S}$ exists. □

3.7.3 Example 6.2 — sequence domain equations

EXAMPLE 6.2. Our staple examples B and C satisfy "domain equations" in the form of isomorphisms as we have previously seen. Indeed

$$B \cong B + B, \text{ and}$$

$$C \cong \{\{\Lambda\}\} + C + C,$$

where if we liked we could construct both systems over $\{0,1\}^*$ and have:

$$B = \{\{0,1\}^*\} \cup \{0X \mid X \in B\} \cup \{1X \mid X \in B\}, \text{ and}$$

$$C = \{\{0,1\}^*\} \cup \{\{\Lambda\}\} \cup \{0X \mid X \in C\} \cup \{1X \mid X \in C\}.$$

We leave to the exercises the explanations of what kinds of algebras B and C are and why they are initial. Here we want to propose a simple, yet interesting generalization of B.

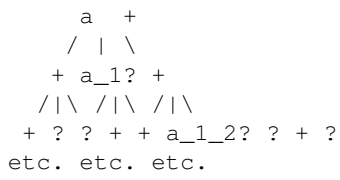
Consider this domain equation:

$$A \cong A^n + A^n,$$

where A^n stands for the n-fold cartesian power of A. We can, with the aid of some encoding solve this equation as a neighbourhood system over $\{0,1\}^*$ as follows:

$$A = \{\{0,1\}^*\} \cup \bigcup_{i=0,1} \left\{ i \bigcup_{j<n} 1^j 0 X_j \mid X_j \in A \text{ for all } j < n \right\}.$$

For instance, if $n = 3$, then a typical neighbourhood in A is something like



$$00X_0 \cup 010X_1 \cup 0110X_2,$$

where $X_0, X_1, X_2 \in A$. The first '0' could also be a '1' in front of each of the terms.

In words, an element of A (other than $\perp$) is an n-tuple of elements of A: but there are two separate copies of these, the left one and the right one. We can write for $a \in |A|$

$$a = \pm\langle a_0, a_1, \ldots, a_{n-1}\rangle,$$

where $+$ is chosen if a is on the right, and $-$ if on the left. As a tree diagram a might look like this for $n = 3$:

That is, a is an infinite ternary tree with $+$ or $-$ labels at each node. If each node (subtree) is truly infinite, the element is *total*; if $\perp$ is ever encountered, it is only *partial*; if every branch ends with $\perp$, the tree is a *finite element* of $|A|$.

What can be done with such trees? Let $\sigma \in \{0, 1, \ldots, n-1\}^*$ be a finite sequence of "digits" each less than n. We let $\Sigma = \{0, 1, \ldots, n-1\}$. We can define for $a \in |A|$ the operation $\sigma \mapsto a\sigma$ by recursion on σ:

$$a\Lambda = a, \text{ and}$$

$$ai\sigma = (a_i)\sigma.$$

The $a\sigma$ are just the *subtrees* of a with σ as a *selector*. We also have a map

$$\mathrm{pos} : A \to T$$

where

$$\mathrm{pos}(+\langle a_0, a_1, \ldots, a_{n-1}\rangle) = \mathrm{true}, \text{ and}$$

$$\mathrm{pos}(-\langle a_0, a_1, \ldots, a_{n-1}\rangle) = \mathrm{false}.$$

We say that a (total) tree a is *eventually periodic* iff the set $\{a\sigma \mid \sigma \in \Sigma^*\}$ is finite. The result is that the "language"

$$L_a = \{\sigma \in \Sigma^* \mid \mathrm{pos}(a\sigma) = \mathrm{true}\}$$

corresponding to an eventually periodic tree is always a *regular event* of automata theory, and every such language has this form. In fact, a just represents the initial state of an automaton, and $a\sigma$ represents the state after "reading" a tape σ. $\square$

In order to formulate more generally the idea of a domain equation and initial algebra, we must introduce a small amount of the terminology of category theory. To be as specific as possible, think of systems D over sets $\Delta \subseteq \Sigma^*$ with $\Sigma = \{0, 1\}$, say. They form quite an interesting category with respect to the approximable maps $f : D \to D'$. Recall that to be a category of "domains" and "maps" all that is required is an associative composition $g \circ f$ of maps with identity maps $I : D \to D$ for each domain of the category. And this we certainly have for the systems indicated. And there are many other categories waiting around: for instance, restrict systems to those where $\emptyset \notin D$. This is not much of a restriction, as every system is isomorphic to one like this. Or restrict the maps to being the strict maps $f : D \to D'$ where $f(\perp_D) = \perp_{D'}$. This is an essentially different, though related category. We shall find many others.

What examples 6.1 and 6.2 suggest is the notion of a construct which makes new domains out of old. For example, with D fixed, 6.1 suggests for any domain X over $\Gamma \subseteq \Sigma^*$ a domain

$$T(X) = D + (X \times X).$$

More specifically (converting from $\Sigma = \{0,1,2\}$ to $\Sigma = \{0,1\}$) we could write

$$T(X) = \{\Gamma'\} \cup \{0X \mid X \in D\} \cup \{10X \cup 11Y \mid X, Y \in X\},$$

where we have $\Gamma' = 0\Delta \cup 10\Gamma \cup 11\Gamma$. (By the way, here we definitely want to assume $\emptyset \notin D$ and $\emptyset \notin X$ and to get $\emptyset \notin T(X)$.) This construct is an example of a *functor*, a notion that can be defined abstractly on any category.

3.7.4 Definition 6.3 — functor

DEFINITION 6.3. A *functor* on a category (into itself) associates with every domain X in the category another domain $T(X)$ and to every map

$$f : X \to Y$$

another map

$$T(f) : T(X) \to T(Y)$$

in such a way that identity maps and compositions are preserved:

$$T(I_X) = I_{T(X)}, \text{ and}$$

$$T(g \circ f) = T(g) \circ T(f),$$

whenever $f : X \to Y$ and $g : Y \to Z$. □

In the example from 6.1 we have not checked how the special **T** is a functor. The hint is that whenever $f : X \to Y$, then there is a map

$$f \times f : X \times X \to Y \times Y.$$

But there is also a map

$$I_D + f \times f : D + (X \times X) \to D + (Y \times Y)$$

and this suggests the definition of $T(f)$. The details are left to the exercises. Note that the map $T(f)$ just suggested is always strict, so **T** is a functor also for the category of strict maps.

One good reason for a little of the category-theoretic language is that the next definition becomes very neat indeed.

3.7.5 Definition 6.4 — algebra for a functor

DEFINITION 6.4. A ***T*-algebra** is a domain E in the category together with a map

$$k : T(E) \to E.$$

If $m : T(F) \to F$ is another ***T*-algebra**, then a *homomorphism* is a map $h : E \to F$ in the category such that the diagram

$$\begin{array}{ccc} T(E) & \xrightarrow{k} & E \\ \downarrow{\scriptstyle T(h)} & & \downarrow{\scriptstyle h} \\ T(F) & \xrightarrow{m} & F \end{array}$$

commutes; that is, the equation

$$h \circ k = m \circ T(h)$$

holds. □

In our example from 6.1 a T-algebra is a *strict* map

$$k : D + (E \times E) \to E.$$

But such strict maps are in a one-one correspondence with pairs of (not necessarily strict) maps

$$n : D \to E \quad \text{and} \quad p : E \times E \to E.$$

And the structure $\langle E, n, p\rangle$ is what we called a tree algebra. Definition 6.4 just makes this abstract. The reader should also work out the details showing that 6.4's definition of homomorphism is just what we ought to expect.

Note that the T-algebras and homomorphisms form a category. (Why?) The following definition is so abstract that it could be given for any category.

end DomainTheory.NeighbourhoodSystems
end
```

3.7.6 Definition 6.5 — initial algebra

DEFINITION 6.5. A T-algebra is *initial* if and only if there is a unique homomorphism from it into any other T-algebra. □

The word "other" here is not meant to imply "distinct". For an initial algebra there is one and only one homomorphism into itself: the identity map. As we already indicated in 6.1 it is a general fact that the next proposition holds.

3.7.8 Proposition 6.7 — functor preserves initiality

PROPOSITION 6.7. If $i : T(D) \to D$ is an initial T-algebra, then so is $T(i) : T^2(D) \to T(D)$ and i is the isomorphism from $T(D)$ to D.

Proof: Clearly since T is a functor, the map $T(i)$ has the right mapping character to make $T(D)$ a T-algebra. Since D is initial, we have a commuting diagram:

$$\begin{array}{ccc} T(D) & \stackrel{i}{\to} & D \\ \downarrow^{T(j)} & & \downarrow^{j} \\ T^2(D) & \xrightarrow{T(i)} & T(D) \end{array}$$

But we also have the trivial diagram:

$$\begin{array}{ccc} T^2(D) & \xrightarrow{T(i)} & T(D) \\ \downarrow{\scriptstyle T(i)} & & \downarrow{\scriptstyle i} \\ T(D) & \xrightarrow{i} & D \end{array}$$

It follows that $i \circ j$ is a homomorphism, so

$$i \circ j = I_D.$$

But then because T is a functor we find:

$$T(i) \circ T(j) = I_{T(D)},$$

and, since j is a homomorphism, we have

$$j \circ i = I_{T(D)}.$$

This shows that i is an isomorphism. □

From 6.7 we see that if we are going to have initial algebras at all we have to satisfy the domain equation

$$D \cong T(D).$$

But generally that is not enough to assure that D is initial. There is a condition that our functors satisfy, however, which guarantees the existence of homomorphisms.

3.7.10 Theorem 6.9 — homomorphism from initial algebra

THEOREM 6.9. If the functor T is continuous on maps and if $D \cong T(D)$, so in particular D is a T-algebra, then for any T-algebra $k : T(E) \to E$ there is a homomorphism $h : D \to E$.

Proof: Let $i : T(D) \to D$ make D a T-algebra, where $j : D \to T(D)$ is the inverse so that i is an isomorphism of domains. Suppose that $k : T(E) \to E$ is any T-algebra. A homomorphism $h : D \to E$ would satisfy

$$h \circ i = k \circ T(h).$$

Rewrite this equation as

$$h = k \circ T(h) \circ j.$$

In the domain of strict maps $(D \to E)$ this is a fixed-point equation for an approximable map

$$\lambda h.\, k \circ T(h) \circ j$$

by our assumption on T. Thus, the desired homomorphism exists. □

The final question we have to answer is why in our category the minimal D exist. The reason is that the functors T that we have in mind possess further continuity properties on domains. This is conveniently expressed in terms of a notion of "subdomain".

open NeighborhoodSystem ApproximableMap

/-- **Definition 6.13, monotone part (pointwise).** Given a subdomain relation `h : D ?
     E`, the data
witnessing that the functor `T` carries it to `T(D) ? T(E)` *and* carries the
    projection pair `i, j`
of 6.12 to the projection pair of `T(D) ? T(E)`.

Because `T` may change the token type, the two image systems live a priori over
    different carriers;
`carrier_eq` records that they coincide, `sub` is the resulting subdomain relation (
    with `T(E)`'s
system transported into `T(D)`'s carrier), and `inj_heq`/`proj_heq` say the canonical
    6.12 maps of
`sub` are `T(i)` and `T(j)` (up to that transport, hence `HEq`). -/
structure MonotoneAt (T : Endofunctor DomainObj.{w}) {a : Type w}
    {D E : NeighborhoodSystem a} (h : D ? E) : Prop where
  /-- The two image carriers coincide, so `T(D) ? T(E)` can be stated. -/
  carrier_eq : (T.obj <a, E>).carrier = (T.obj <a, D>).carrier
  /-- The image subdomain relation `T(D) ? T(E)` (with `T(E)`'s system carried into `T(
    D)`'s
  carrier). -/
  sub : (T.obj <a, D>).sys ?
    (carrier_eq  |>  (T.obj <a, E>).sys : NeighborhoodSystem (T.obj <a, D>).carrier)
  /-- The injection of `T(D) ? T(E)` is `T(i)` (Scott: the pair is mapped to `T(i), T(j
    )`). -/
  inj_heq : HEq (T.map (X := <a, D>) (Y := <a, E>) h.inj) sub.inj
  /-- The projection of `T(D) ? T(E)` is `T(j)`. -/

end DomainTheory.NeighbourhoodSystems
end
```

3.7.11 Definition 6.10 — subdomain

DEFINITION 6.10. For two neighbourhood systems D and E we write

$$D \triangleleft E$$

to mean that these are neighbourhood systems over the same set of tokens Δ and not only is $D \subseteq E$ but whenever $X, Y \in D$ and $X \cap Y \in E$, then $X \cap Y \in D$. $\square$

For the subdomain relation $D \lhd E$ to hold, D has to be a smaller family of neighbourhoods, but the notion of consistency in D also has to be the same as in E. Note that if $D_0 \lhd E$ and $D_1 \lhd E$ then

$$D_0 \lhd D_1 \text{ iff } D_0 \subseteq D_1.$$

It is also easy to prove that the union of a directed family of subdomains of E is again a subdomain. As a consequence of this remark we have:

/- concordance: source L3799 DEFINITION 6.10 subdomain -/
/-- **Definition 6.10 (Scott 1981, PRG-19).** The *subsystem* (subdomain) relation `D ?
     E` for two
neighbourhood systems over the same token type. It records that `D` and `E` are systems
     over the
same `Delta` (`master_eq`), that `D` is a subfamily of `E` (`sub`), and -- the essential
     clause -- that
consistency is inherited from `E`: an intersection of two `D`-neighbourhoods that
    happens to be an
`E`-neighbourhood is already a `D`-neighbourhood (`inter_closed`). -/
structure Subsystem (D E : NeighborhoodSystem a) : Prop where
  /-- `D` and `E` are systems over the same set of tokens `Delta`. -/
  master_eq : D.master = E.master
  /-- `D  subseteq  E`: every neighbourhood of `D` is a neighbourhood of `E`. -/
  sub : forall  {X : Set a}, D.mem X  ->  E.mem X
  /-- Consistency in `D` is the same as in `E`: if `X, Y  in  D` and `X  I  Y  in  E`,
    then `X  I  Y  in  D`. -/
  inter_closed : forall  {X Y : Set a}, D.mem X  ->  D.mem Y  ->  E.mem (X  I  Y)  ->

3.7.13 Proposition 6.12 — projection pair

PROPOSITION 6.12. If $D \triangleleft E$, then there exists a projection pair of approximable mappings:

$$i : D \to E \quad \text{and} \quad j : E \to D$$

where $j \circ i = I_D$ and $i \circ j \subseteq I_E$, which are determined as element-wise functions by these equations:

$$i(x) = \{Y \in E \mid \exists X \in x.\, X \subseteq Y\},$$

and

$$j(y) = y \cap D,$$

for all $x \in |D|$ and $y \in |E|$. □

The proof is left for the exercises.

3.7.14 Definition 6.13 — continuity on domains

DEFINITION 6.13. A functor T is *monotone on domains* iff whenever $D \triangleleft E$, then not only do we have $T(D) \triangleleft T(E)$ but the projection pair i, j of 6.12 is mapped to the same kind of projection pair $T(i), T(j)$. A monotone functor is *continuous on domains* iff whenever E is a domain, then the mapping

$$\lambda D.\, T(D) : \{D \mid D \triangleleft E\} \to \{D' \mid D' \triangleleft T(E)\}$$

is approximable. □

We can now state an existence theorem that covers in fairly wide generality the examples of this lecture.

3.7.15 Theorem 6.14 — existence of initial algebras

THEOREM 6.14. If the functor T is continuous on maps and monotone and continuous on domains, and if there is a set Γ such that

$$\{\Gamma\} \lhd T(\{\Gamma\}),$$

then there exists an initial T-algebra.

Proof: We proceed as in the proof of the fixed-point theorem by iterating the functor. The assumption about Γ means that, as a neighbourhood system, $T(\{\Gamma\})$ is a system over the same set Γ. Thus, if we iterate T to form $T^n(\{\Gamma\})$, all these systems are over Γ and indeed

$$T^n(\{\Gamma\}) \lhd T^{n+1}(\{\Gamma\})$$

for all n. We can thus introduce

$$\mathcal{D} = \bigcup_{n=0}^{\infty} T^n(\{\Gamma\}),$$

and it is easy to check that $\mathcal{D}$ is a system over Γ and

$$T^n(\{\Gamma\}) \lhd \mathcal{D}$$

holds for all n. But then we have for all n:

$$T^n(\{\Gamma\}) \lhd T^{n+1}(\{\Gamma\}) \lhd T(\mathcal{D}),$$

which implies $\mathcal{D} \lhd T(\mathcal{D})$. But T is continuous on domains, so

$$\begin{aligned} T(\mathcal{D}) &= T\left(\bigcup_{n=0}^{\infty} T^n(\{\Gamma\})\right) \\ &= \bigcup_{n=0}^{\infty} T^{n+1}(\{\Gamma\}) \\ &= \mathcal{D}. \end{aligned}$$

Thus, not only is $\mathcal{D}$ a T-algebra, but the isomorphism we get for $\mathcal{D}$ and $T(\mathcal{D})$ is just the identity mapping. We know by 6.9 that homomorphisms exist; what remains to show is that homomorphism from $\mathcal{D}$ are unique. As in the examples, we will show in effect they are determined uniquely on the finite elements of $\mathcal{D}$.

Since each $T^n(\{\Gamma\}) \lhd \mathcal{D}$, there are projection mappings $i_n : T^n(\{\Gamma\}) \to \mathcal{D}$ and $j_n : \mathcal{D} \to T^n(\{\Gamma\})$.

Define $\rho_n : \mathcal{D} \to \mathcal{D}$ by $\rho_n = i_n \circ j_n$. Projection pairs are always pairs of strict mappings (Why?), and so are in the category. By assumption and 6.13, the functor T preserves these maps, so we have

$$T(\rho_n) = T(i_n) \circ T(j_n) = i_{n+1} \circ j_{n+1} = \rho_{n+1}.$$

As a neighbourhood relation ρ_n can be characterized by :

$$X \rho_n Y \quad \text{iff} \quad \exists z \in T^n(\{\Gamma\}).\ X \subseteq z \subseteq Y.$$

We thus see that $\rho_n \subseteq \rho_{n+1}$ and

$$\bigcup_{n=0}^{\infty} \rho_n = I_{\mathcal{D}}.$$

Now suppose $k : T(E) \to E$ is any T-algebra and $h : \mathcal{D} \to E$ is a homomorphism. The mapping will satisfy the fixed-point equation

$$h = k \circ T(h),$$

where no other mappings need be written in because $\mathcal{D} = T(\mathcal{D})$ and so

$$T(h) : \mathcal{D} \to T(E).$$

We wish to show that h really is the least fixed point of this equation.

Define $h_n = h \circ \rho_n : \mathcal{D} \to E$. For $n = 0$, the map ρ_0 is the trivial map where $\rho_0(x) = \bot_{\mathcal{D}}$ for all $x \in |\mathcal{D}|$. But h must be strict, so $h_0(x) = \bot_E$ for all $x \in |\mathcal{D}|$; that is, h_0 is the least element of $|\mathcal{D} \to_\bot E|$. Now calculate :

$$\begin{aligned} k \circ T(h_n) &= k \circ T(h) \circ T(\rho_n) \\ &= h \circ \rho_{n+1} \\ &= h_{n+1} \, . \end{aligned}$$

This shows that the union of the h_n is the least fixed point of $\lambda h.\, k \circ T(h)$. But

$$\begin{aligned} \bigcup_{n=0}^{\infty} h_n &= \bigcup_{n=0}^{\infty} h \circ \rho_n \\ &= h \circ \bigcup_{n=0}^{\infty} \rho_n \\ &= h \circ I_D = h, \end{aligned}$$

so the given h is in fact the least fixed point. The homomorphism is uniquely determined, and D is the initial T-algebra. □

Having the existence of initial T-algebras, we can prove one more result that shows just how minimal they are. We need a lemma about projection pairs, first, that shows where sub-domains fit in. We write $D \trianglelefteq E$ as short for $D \cong D'$ for some $D' \triangleleft E$ in the following. The lemma gives a converse to 6.12.

3.7.16 Lemma 6.15 — subdomains from projection pairs

LEMMA 6.15. For two neighbourhood systems D and E, if there exist a projection pair

$$i : D \to E \quad \text{and} \quad j : E \to D$$

with $j \circ i = I_D$ and $i \circ j \subseteq I_E$, then $D \trianglelefteq E$.

Proof. What we want to show is that i maps finite elements to finite elements, and that the desired D' is the image of D in E.

Suppose $X \in D$. We can write:

$$i(\uparrow X) = \bigcup \{\uparrow Y \mid Y \in i(\uparrow X)\} .$$

Applying j to both sides we have:

$$\uparrow X = j \circ i(\uparrow X) = \bigcup \{j(\uparrow Y) \mid Y \in i(\uparrow X)\}.$$

But then, since $X \in \uparrow X$, we find $X \in j(\uparrow Y)$ for some $Y \in i(\uparrow X)$. This implies

$$\uparrow X \subseteq j(\uparrow Y); \text{ and so } i(\uparrow X) \subseteq i \circ j(\uparrow Y) \subseteq \uparrow Y.$$

Since $\uparrow Y \subseteq i(\uparrow X)$ in any case, we conclude $i(\uparrow X) = \uparrow Y$. This proves finite elements are mapped to finite elements.

What of Δ; that is, what is $i(\uparrow \Delta)$? We find, supposing E to be a neighbourhood system over a set Δ', that since $\uparrow \Delta \subseteq j(\uparrow \Delta')$, then $i(\uparrow \Delta) \subseteq \uparrow \Delta'$ and so $i(\uparrow \Delta) = \uparrow \Delta'$. This means that Δ corresponds to Δ'. So we have established that $\mathcal{D}$ is in an inclusion preserving one-one correspondence with a subset $\mathcal{D}'$ of E where $\Delta' \in \mathcal{D}'$. But it remains to show that $\mathcal{D}'$ is a neighbourhood system and that $\mathcal{D}' \lhd E$ holds. All we really have to show is that $\mathcal{D}'$ is closed under intersection whenever the intersection belongs to E.

Suppose $Y', Z' \in \mathcal{D}'$ and $Y' \cap Z' \in E$. Let $X' = Y' \cap Z'$. We have, for suitable $Y, Z \in \mathcal{D}$,

$$i(\uparrow Y) = \uparrow Y', \text{ and so } \uparrow Y = j(\uparrow Y'); \text{ and}$$

$$i(\uparrow Z) = \uparrow Z', \text{ and so } \uparrow Z = j(\uparrow Z').$$

But $\uparrow Y' \subseteq \uparrow X'$ and $j(\uparrow Y') \subseteq j(\uparrow X')$; thus $Y \in j(\uparrow X')$. For similar reasons $Z \in j(\uparrow X')$. But then $X = Y \cap Z \in j(\uparrow X')$, and therefore $Y \cap Z \in \mathcal{D}$. (The element $j(\uparrow X')$ must be a filter.) Notice, however, that

$$\uparrow Y \subseteq \uparrow X, \text{ and so } \uparrow Y' \subseteq i(\uparrow X); \text{ and}$$

$$\uparrow Z \subseteq \uparrow X, \text{ and so } \uparrow Z' \subseteq i(\uparrow X).$$

It follows that $Y' \cap Z' = X' \in i(\uparrow X)$. On the other hand we already knew $X \in j(\uparrow X')$, which implies $i(\uparrow X) \subseteq \uparrow X'$. We may thus conclude that $i(\uparrow X) = \uparrow X'$. In other words $X' \in \mathcal{D}'$. □

3.7.17 Theorem 6.16 — initial algebra is minimal

THEOREM 6.16. If on the category of domains and strict approximable maps the functor T is continuous on maps, and if D is an initial T-algebra, then for any system $E \cong T(E)$ we have $D \trianglelefteq E$.

Proof: There is a homomorphism $h : D \to E$. By 6.9 there is a homomorphism $g : E \to D$. Now $g \circ h : D \to D$ is also a homomorphism, so $g \circ h = I_D$ because D is initial. In view of 6.15, all we have to prove now is that $h \circ g \sqsubseteq I_E$.

Let the maps $i : T(D) \to D$ and $j : D \to T(D)$ give the isomorphism for D, and let $u : T(E) \to E$ and $v : E \to T(E)$ do the same for E. By the proof of 6.9 we know

$$g = i \circ T(g) \circ v \quad \text{and} \quad h = u \circ T(h) \circ j$$

and each of these maps is the least fixed point of its respective equation. Let

$$g_0 = \bot_{E \to D} \quad \text{and} \quad h_0 = \bot_{D \to E}$$

and define by recursion

$$g_{n+1} = i \circ T(g_n) \circ v \quad \text{and} \quad h_{n+1} = u \circ T(h_n) \circ j.$$

By the fixed-point calculation

$$g = \bigsqcup_{n=0}^{\infty} g_n \quad \text{and} \quad h = \bigsqcup_{n=0}^{\infty} h_n.$$

Now we see that

$$h_0 \circ g_0 = \bot_{E \to E},$$

and for each n that

$$\begin{aligned} h_{n+1} \circ g_{n+1} &= u \circ T(h_n) \circ j \circ i \circ T(g_n) \circ v \\ &= u \circ T(h_n) \circ T(g_n) \circ v \\ &= u \circ T(h_n \circ g_n) \circ v. \end{aligned}$$

But this means that

$$h \circ g = \bigsqcup_{n=0}^{\infty} (h_n \circ g_n)$$

is the least fixed point for the equation

$$k = u \circ T(k) \circ v.$$

But I_E is one of the fixed points; whence $h \circ g \sqsubseteq I_E$ must follow. □

EXERCISES

3.7.19 Exercise 6.17 — algebras for sequence domains

What are the algebras for which C is initial? If A of 6.2 is a generalization of B, what is the corresponding generalization of C? Prove that it exists and explain what are the algebras involved.

Exercise_6_17.lean

3.7.20 Exercise 6.18 — infinite product as initial

With reference back to Exercise 3.16 discuss the construction of $\mathcal{D}^\infty$ as an initial algebra and as a solution to the domain equation

$$\mathcal{D}^\infty \cong \mathcal{D} \times \mathcal{D}^\infty.$$

(I do not know whether all solutions must be of the form $\mathcal{D}^\infty \times E$.)

/-- **Exercise 6.18 (initial-algebra half) -- `?^ inf ` is the initial `T`-algebra for
    `T(X) = ?  x  X`.**
For every `T`-algebra `(E, k)` the descent map `h(<x_0,x_1,...>) = k(x_0, k(x_1, ...))`
     is the *unique*
strict homomorphism `?^ inf   ->  E`. Together with Exercise 3.16's `?^ inf   ~=  ?  x
     ?^ inf ` (the domain-equation
half), this exhibits `?^ inf ` both as the canonical solution of the domain equation
    and as the initial
algebra (determined up to iso by Proposition 6.6). -/

3.7.21 Exercise 6.19 — strict sum and product

For the sake of uniformity restrict attention to systems $\mathcal{D}$ on sets $\Delta \subseteq \{0,1\}^*$, where $\Lambda \in \Delta$ and $\emptyset \notin \mathcal{D}$, and to the category of strict maps. Define sum and product by:

$$\mathcal{D}_0 + \mathcal{D}_1 = \{\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1\} \cup \{0X \mid X \in \mathcal{D}_0\} \cup \{1Y \mid Y \in \mathcal{D}_1\},$$

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{\{\Lambda\} \cup 0X \cup 1Y \mid X \in \mathcal{D}_0 \text{ and } Y \in \mathcal{D}_1\}.$$

Are these correct up to isomorphism? Now generate all constructs $T(X)$ formed by the constants (that is, $T(X) = \mathcal{D}$ for a fixed $\mathcal{D}$), by the identity ($T(X) = X$), and by sums and products ($T_0(X) + T_1(X)$, etc.). Show that these are all functors, continuous on maps, and monotone and continuous on domains.

3.7.22 Exercise 6.20 — tokens of a functor

For any system $\mathcal{D}$ let $\mathrm{tok}(\mathcal{D})$ be the underlying set of tokens, so that $\mathcal{D}$ is a system over $\mathrm{tok}(\mathcal{D})$. For the category of Exercise 6.19 show that the function

$$\lambda\Gamma.\,\mathrm{tok}(T(\{\Gamma\}))$$

is continuous on the domain $\{\Gamma \subseteq \{0,1\}^* \mid \Lambda \in \Gamma\}$, where T is any of the functors generated in 6.19. Conclude that there must exist a set

$$\Gamma = \mathrm{tok}(T(\{\Gamma\})),$$

so that $\{\Gamma\} \triangleleft T(\{\Gamma\})$, and so 6.14 applies.

3.7.23 Exercise 6.21 — coalesced sum and smash

Do the same as 6.19 and 6.20 when the functors are also allowed to be generated by the operations:

$$D_0 \oplus D_1 = \{\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1\} \cup \{0X \mid X \in D_0 \setminus \{\Delta_0\}\} \cup \{1Y \mid Y \in D_1 \setminus \{\Delta_1\}\},$$

$$D_0 \otimes D_1 = \{\{\Lambda\} \cup 0\Delta_0 \cup 1\Delta_1\} \cup \{\{\Lambda\} \cup 0X \cup 1Y \mid X \in D_0 \setminus \{\Delta_0\} \text{ and } Y \in D_1 \setminus \{\Delta_1\}\}.$$

Generalize all of $+$, $\times$, $\oplus$, $\otimes$ to combinations of several terms, not just the binary sums and products.

3.7.24 Exercise 6.22 — equations for the integers

Comment on these domain equations:

$$N \cong \{\{0\}, \{0, \Lambda\}\} \oplus N,$$

$$M \cong \{\{\Lambda\}\} + M,$$

$$N^* \cong N \oplus (N \otimes N^*).$$

3.7.25 Exercise 6.23 — syntactic expression domain

Construe the initial solution to

$$Exp \cong N \oplus ((Exp \times Exp) + (Exp \times Exp))$$

as a "syntactical domain" of expressions generated from infinitely many "variables" by means of two binary "operation symbols". Given an algebra D with two operations

$$u : D \times D \to D \quad \text{and} \quad v : D \times D \to D,$$

show how any strict map $s : N \to D$ determines a unique map

$$val(s) : Exp \to D$$

that can be regarded as the "evaluation of an expression".

3.7.26 Exercise 6.24 — recursive domain equations

Show that there must exist domains satisfying:

$$D \cong D + (D \times E), \quad \text{and}$$

$$E \cong D + E,$$

by using a double fixed-point method. First decide what the underlying set of tokens should be, and then define D and E by simultaneous fixed points. (Syntactical domains as in 6.23 may very well require several simultaneous equations.)

Exercise_6_24.lean

3.7.27 Exercise 6.25 — projection pair laws

For a projection pair $g : \mathcal{D} \to \mathcal{E}$ and $h : \mathcal{E} \to \mathcal{D}$ show that for $x \in |\mathcal{D}|$ and $y \in |\mathcal{E}|$ we have:

$$g(x) \sqsubseteq y \text{ iff } x \sqsubseteq h(y).$$

Thus, conclude that:

$$h(y) = \bigsqcup \{x \in |\mathcal{D}| \mid g(x) \sqsubseteq y\}, \quad \text{and}$$

$$g(x) = \bigsqcap \{y \in |\mathcal{E}| \mid x \sqsubseteq h(y)\},$$

for all $x \in |\mathcal{D}|$ and $y \in |\mathcal{E}|$. So each of the functions determines the other. In the first equation check that the set on the right is directed, and in the second equation that the set on the right is non empty. Prove also that g maps consistent sets to consistent sets and preserves $\bigsqcup$ (not just directed unions).

3.7.28 Exercise 6.26 — lifting a domain

For systems $\mathcal{D}$ as in 6.19 define

$$\mathcal{D}_\perp = \{\{\Lambda\} \cup 0\Delta\} \cup \{0X \mid X \in \mathcal{D}\}.$$

Describe the construct in terms of elements. Is this a suitable functor? Prove that

$$\mathcal{D}_\perp \oplus \mathcal{E}_\perp \cong \mathcal{D} + \mathcal{E}.$$

What is

$$\mathcal{D}_\perp \otimes \mathcal{E}_\perp \cong ??$$

3.7.29 Exercise 6.27 — which embeddings hold

Which of the following relationships are true:

$$(\mathcal{D} \otimes \mathcal{E}) \trianglelefteq (\mathcal{D} \times \mathcal{E})\,; \quad \mathcal{D} \trianglelefteq \mathcal{D} \times \mathcal{E}\,;$$

$$(\mathcal{D} \oplus \mathcal{E}) \trianglelefteq (\mathcal{D} + \mathcal{E})\,; \quad \mathcal{D} \trianglelefteq \mathcal{D} \oplus \mathcal{E}\,;$$

$$(\mathcal{D} \to_{\perp} \mathcal{E}) \trianglelefteq (\mathcal{D} \to \mathcal{E})\,; \quad \mathcal{D} \trianglelefteq \mathcal{D} \otimes \mathcal{E}\,?$$

3.8 Computability in effectively given domains

Dependency diagram. Each box is one item. The arrowhead is on the item that imports. An arrow already implied by a longer path is left out. The introduction has no Lean file, so it is not shown. Blue is a definition, green a proposition, amber an example, red a theorem, and indigo an exercise.

3.8.1 Introduction

LECTURE VII COMPUTABILITY IN EFFECTIVELY GIVEN DOMAINS

For the domain N the strict functions from N into N, the strict maps $f : N \to N$, correspond exactly to the partial functions $g : N \to N$ (as we wrote in 5.6 we had $f = \bar{g}$). For such functions there is a standard theory of computability: g is called computable if it can be defined as a partial recursive function with its "program" written down in a certain standard form. The non-strict maps $h : N \to N$ are all constant, and

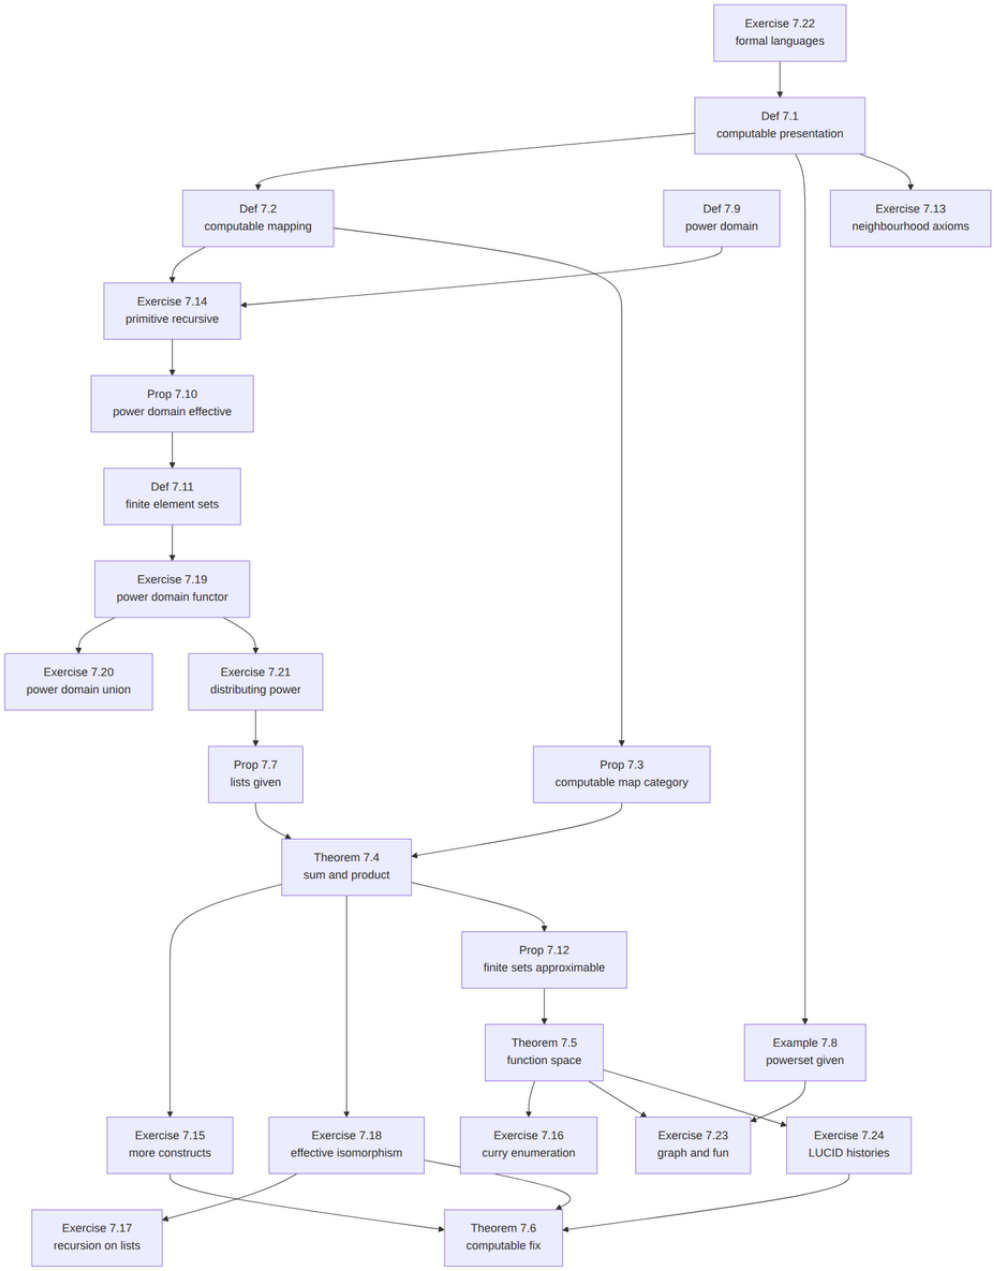

Figure 36: Computability in effectively given domains.

so are intuitively computable; so we know all about computable maps in $|N \to N|$ in general. The question is: what are the computable maps on (elements of) other domains?

The answer will of course depend on how the domain is presented to us. Even with N, there are continuum many isomorphisms $\pi : N \to N$ of N onto itself, not all of which can be computable. That is, if we permute N and, so to speak, present the integers in a different order, then a well-behaved computable function $f : N \to N$ may well be transformed into a non-computable function,

$$\pi \circ f \circ \pi^{-1} : N \to N.$$

(Hint: Consider the characteristic function e of the even numbers. Take $f = \bar{e}$ and let π be very horrid.) The reason we imagined we knew which were the computable $f : N \to N$ is that N is always thought of in a standard presentation. We must thus define "in general" a concept of an *effectively given domain*, that is to say, one with a sufficiently computable presentation to represent the additional knowledge about the domain.

The main idea will be that the *finite elements* of $|D|$ should be regarded as the ones initially known. Abstractly, to know a finite element is to know how it is *related* to other finite elements.

Of course, this will mean that we will allow at most a countable infinity of finite elements — but this restriction well accords with intuition. To make precise the terminology "related to" it proves most convenient to go back to the neighbourhoods (in any case they are in a one-one correspondence with the finite elements).

3.8.2 Definition 7.1 — computable presentation

DEFINITION 7.1. A neighbourhood system D has a *computable presentation* provided we can write

$$D = \{X_n \mid n \in N\},$$

where the following two relations

(i) $X_n \cap X_m = X_k$; and

(ii) $\exists k \in N.\, X_k \subseteq X_n$ and $X_k \subseteq X_m$

are recursively decidable (in integer indices n, m, k and in n, m, respectively). □

More strictly the sequence,

$$\langle X_n \rangle_{n=0}^{\infty},$$

is the presentation. Even more strictly, when it is required to cope with infinitely many domains at a time, it would be necessary to give the actual Gödel numbers of the recursive relations (i) and (ii) (rather than just saying there exists some way of showing them to be recursively decidable).

The intuitive idea of 7.1 is that the system is effectively given if you know how to do elementary "calculations" with neighbourhoods. The basic calculations are the forming of intersections. The neighbourhoods have to be laid out in a systematic way; and, if we are asked for an intersection of two given neighbourhoods, we have to be able to locate it in the standard sequence. Relation (ii) is the *consistency condition* , which is the necessary and sufficient condition for the intersection to exist in D. When (ii) is true, therefore, we have only to try $k = 0, 1, 2, \ldots$ until we discover that we have found the intersection. We are

assuming that these basic decisions can be carried out in "finite time". Note that the obvious biconditional,

$$X_n \subseteq X_m \text{ iff } X_n \cap X_m = X_n,$$

assures us that the inclusion relation between neighbourhoods is itself decidable in terms of the indices. So in (ii) if k exists, *then* it (or the first one) can indeed be found in finite time. The rub is that if it *does not exist*, no finite number of inclusion checks will determine that fact. That is why we have to *assume* that (ii) is always decidable. The information contained in (ii) is a fundamental part of the neighbourhood structure. (An axiomatic characterization of neighbourhood structures is given in Exercise 7.13, which may make clearer what we are assuming and what a presentation is.)

variable {a : Type*}

/-- **Definition 7.1 (Scott 1981, PRG-19).** A *computable presentation* of a
    neighbourhood system
`V` over a token type `a`: an enumeration `X : Nat  ->  Set a` whose range is exactly
    `?` (`mem_X` and
`surj`), such that Scott's two relations on the integer indices are recursively
    decidable:

* `interEq_computable` is (i): the ternary relation `X_n  I  X? = X_k`;
* `cons_computable` is (ii): the binary consistency relation `exists  k. X_k  subseteq
     X_n  I  X?`
  (Scott's `X_k  subseteq  X_n and X_k  subseteq  X?`).

Only the enumeration `X` is data; the remaining fields are `Prop`s, so a presentation
    is built
choice-free. -/
structure ComputablePresentation (V : NeighborhoodSystem a) where

3.8.3 Definition 7.2 — computable mapping

DEFINITION 7.2. Given two recursively presented domains,

$$\mathcal{D} = \{X_n \mid n \in \mathbf{N}\} \text{ and } E = \{Y_m \mid m \in \mathbf{N}\},$$

an approximable mapping $f : \mathcal{D} \to E$ is said to be *computable* iff the relation

$$X_n f Y_m$$

is recursively enumerable in n and m. □

The question to ask first is why "recursively enumerable" rather than "recursive" (= "recursively decidable")? The answer will become clear when we let $\mathcal{D}$ degenerate to the one-element domain, $\mathcal{D} = \{\Delta\}$. Then what we are considering is merely a single element

$$y = f(\{\Delta\}) \in |E|.$$

Therefore, 7.2 incorporates the notion of a *computable element* of a domain. And the condition reduces to the statement that the filter $y \in |E|$ is such that the set

$$\{m \in \mathbf{N} \mid Y_m \in y\}$$

is a recursively enumerable set of integers. The point is that the elements of $|E|$ are finite or infinite. If y were finite, the set of indices above would indeed be recursive in view of

our assumptions on E. But an infinite element can in general only be approximated "a little at a time". We cannot expect to know the whole story of its approximations in a flash. What it means to be recursively enumerable is that there is a primitive recursive function (hence, a total function), $r : \mathbf{N} \to \mathbf{N}$, such that

$$y = \{Y_{r(i)} \mid i \in \mathbf{N}\}.$$

That is to say, *all* the approximations to y can eventually be listed. In the case of the mapping f we could write

$$f = \{(X_{s(i)}, Y_{r(i)}) \mid i \in \mathbf{N}\},$$

for a suitable pair of primitive recursive functions s and r.

Definitions 7.1 and 7.2 may very well irritate the person hearing them for the first time: instead of explaining computability in direct terms, the whole question is thrown into the lap of recursion theory! There are several answers. "You have to start somewhere" is one thing I always say. Recursion on the integers is a well-understood theory, and we shall not need the refined parts of the development, fortunately. In any case, our definitions apply to *many* domains of quite different structure, not just to the domain $\mathbf{N}$. And the next step we shall take is to show how to build up computable functions (and also effectively given domains) from simpler ones. Thus, often it will not be necessary to go back to the seemingly over-precise definitions involving the indices but to appeal to some broad general principles.

3.8.4 Proposition 7.3 — computable maps form a category

PROPOSITION 7.3. The identity map on an effectively given domain is computable; the composition of computable mappings on effectively given domains is again computable. □

The proofs for 7.3 are so trivial they are hardly worth an exercise. Note the immediate and useful consequence: if $f : D \to E$ is computable and $x \in |D|$ is computable, then $f(x) \in |E|$ is also computable. The next result is, however, worth working out even though it is quite easy.

3.8.5 Theorem 7.4 — sum and product effective

THEOREM 7.4. If $\mathcal{D}_0$ and $\mathcal{D}_1$ are effectively given, then so are $(\mathcal{D}_0 + \mathcal{D}_1)$ and $(\mathcal{D}_0 \times \mathcal{D}_1)$.

Moreover the combinators in_i and out_i and proj_i^2 are all computable; further, if f and g are computable maps, then so are $f + g$ and $f \times g$.

Proof: Let the computable presentations be given as:

$$\mathcal{D}_i = \{X_n^i \mid n \in \mathbf{N}\}.$$

We can assume that the sets of tokens Δ_0 and Δ_1 are disjoint and $\emptyset \notin \mathcal{D}_i$. Then the construction of the sum is just

$$\mathcal{D}_0 + \mathcal{D}_1 = \{\Delta_0 \cup \Delta_1\} \cup \mathcal{D}_0 \cup \mathcal{D}_1.$$

As an enumeration we define for $n \in \mathbf{N}$:

$$Z_0 = \Delta_0 \cup \Delta_1 \; ; \; Z_{2n+1} = X_n^0 \; ; \; Z_{2n+2} = X_n^1 \; .$$

We leave as an exercise the check of 7.1(i)–(ii).

For the product we want:

$$\mathcal{D}_0 \times \mathcal{D}_1 = \{X_n^0 \cup X_m^1 \mid n, m \in \mathbf{N}\}.$$

What we then need are recursive functions $p : \mathbf{N} \to \mathbf{N}$, $q : \mathbf{N} \to \mathbf{N}$, and $r : \mathbf{N} \times \mathbf{N} \to \mathbf{N}$ where for $m, n, k \in \mathbf{N}$ we have:

$$p(r(n,m)) = n \text{ and } q(r(n,m)) = m, \text{ and } r(p(k), q(k)) = k.$$

Thus r is a "one-one pairing function"; there are many ways to find such functions (see Exercise 5.13). We can then define for $k \in \mathbf{N}$:

$$W_k = X_{p(k)}^0 \cup X_{q(k)}^1 \; .$$

Again we leave as an exercise the check that this provides a computable presentation of $\mathcal{D}_0 \times \mathcal{D}_1$.

As for the combinators, the neighbourhood relations have to be worked out in terms of the indices. For example

$$X_n^0 \; \mathrm{in}_0 \; Z_m \text{ iff either } m = 0 \text{ or for some } k$$

$$m = 2k + 1 \text{ and } X_n^0 \subseteq X_k^0 \; .$$

and

$$W_k \operatorname{proj}_1^2 X_m^1 \text{ iff } X_{q(k)}^1 \subseteq X_m^1 .$$

The reader needs to check that these are recursively enumerable

Relations in the indices. For this purpose it may be convenient to recall some closure properties of these relations: taking conjunctions, disjunctions, substituting recursive functions, applying an existential quantifier to the front. □

Products give us a way of providing an immediate meaning to the notion of a computable function of several variables. Note that the proof of 3.7 is "effective" and shows that substitution of computable functions of several variables into each other always gives computable functions. We turn next to the function spaces.

3.8.6 Theorem 7.5 — function space effective

THEOREM 7.5. If $\mathcal{D}_0$ and $\mathcal{D}_1$ are effectively given, then so is $(\mathcal{D}_0 \to \mathcal{D}_1)$. The combinators eval and curry are computable, provided all the domains involved are effectively given. The computable elements $f \in |\mathcal{D}_0 \to \mathcal{D}_1|$ are exactly the computable maps $f : \mathcal{D}_0 \to \mathcal{D}_1$.

Proof: The proofs of 3.9, 3.11, and 3.12 were set up with this theorem in mind. If

$$\mathcal{D}_0 = \{X_n \mid n \in \mathbf{N}\} \quad \text{and} \quad \mathcal{D}_1 = \{Y_m \mid m \in \mathbf{N}\}$$

are two effectively given neighbourhood systems, then the neighbourhoods of $(\mathcal{D}_0 \to \mathcal{D}_1)$, by Definition

3.8, are non-empty intersections like

$$\bigcap_{i<q}[X_{n_i}, Y_{m_i}],$$

where $\langle n_0, n_1, \ldots, n_{q-1}\rangle$ and $\langle m_0, m_1, \ldots, m_{q-1}\rangle$ are two finite sequences of integers determining the choice of the function-space neighbourhood. In 3.9(i) the test for nonemptiness is given. Assuming the decidability of relations in $\mathcal{D}_0$ and $\mathcal{D}_1$, one remarks that the consistency of *finite sequences* of neighbourhoods is also decidable. (Hint: Test the first *two*, then form their intersection. Next test the third given neighbourhood against this one set; if consistent, form the intersection, and carry on.) By 3.9(i) at most $2 \cdot 2^q$ such sequential checks must be carried out to determine whether the function-space neighbourhood is non empty.

It may not be fun, but the checks can be carried out in finite time. Owing to this decidability, we can therefore enumerate in a systematic way *all* the pairs of finite sequences $\langle n_0, \ldots\rangle$ and $\langle m_0, \ldots\rangle$ that determine neighbourhoods: that is the way that $(\mathcal{D}_0 \to \mathcal{D}_1)$ obtains its enumeration.

Concerning the decidability of the required relations on $(\mathcal{D}_0 \to \mathcal{D}_1)$, we remark first off that consistency is more of the same: to test two finite intersections against each other, just form one big intersection and test it for non-emptiness as before. Secondly, the testing for intersection comes down in the end to testing one typical intersection of $[X, Y]$-neighbourhoods for equality with another. But equality amounts to two inclusions; inclusion in an intersection amounts to inclusion in each term. Therefore, what we need to do is to check a finite number of statements of the form:

$$\bigcap_{i<q}[X_{n_i}, Y_{m_i}] \subseteq [X_k, Y_\ell].$$

As we pointed out after the proof of 3.9, this inclusion is equivalent to

$$\bigcap\{Y_{m_i} \mid X_k \subseteq X_{n_i}\} \subseteq Y_\ell.$$

By decidability in $\mathcal{D}_0$, we can effectively find the n_i that are needed. Then in $\mathcal{D}_1$, we form the intersection of the corresponding Y_{m_i}. Finally, we check the inclusion. Again, one check in $(\mathcal{D}_0 \to \mathcal{D}_1)$ requires a whole sequence of checks in $\mathcal{D}_0$ and in $\mathcal{D}_1$, but the process is finite. So we have argued that $(\mathcal{D}_0 \to \mathcal{D}_1)$ is effectively given.

In showing that the combinators are computable, we refer first to the proof of 3.11. The typical pair of neighbourhoods possibly belonging to eval is

$$\bigcap_{i<q}[X_{n_i}, Y_{m_i}],\ X_k \text{ eval } Y_\ell.$$

As we needed not to be so specific, we expressed the holding of this relationship in terms of *all* the functions in the function-

space neighbourhood. But we know that the neighbourhood, by 3.9(ii), has a minimal element; it is then sufficient to test for the holding of $X_k f_0 Y_\ell$ at this minimal function f_0. But this test, we have already seen, is decidable. So the pairs in eval actually form a recursive set, not just a recursively enumerable set; thus, eval is a computable function.

The case of curry involves three domains and is a bit more messy. But again, if the required neighbourhoods are written out in full, it will be seen that curry, too, is computable. We leave this minor struggle to the exercises.

The final statement is an easy consequence of the fundamental connection between approximable $f : \mathcal{D}_0 \to \mathcal{D}_1$ as relations and as elements. Recall, as in the proof of 3.10, that we have

$$f \in [X, Y] \text{ iff } X f Y,$$

for all $X \in \mathcal{D}_0$ and $Y \in \mathcal{D}_1$. Therefore,

$$f \in \bigcap_{i<q} [X_{n_i}, Y_{m_i}] \text{ iff } \forall i < q.\, X_{n_i} f Y_{m_i}.$$

It follows that if f is recursively enumerable as a set of pairs, then, by forming all the non-empty intersections (as shown), we get an enumeration of all the neighbourhoods to which f belongs; and this is the same as the filter corresponding to f as an element of the function space. The converse direction is clear. □

We have nearly all our favourite combinators computable, but perhaps the most important one - since it is the key to recursive definitions - is the fixed-point combinator. It is not left out.

3.8.7 Theorem 7.6 — fix is computable

THEOREM 7.6. For any effectively given domain $\mathcal{D}$, the combinator fix : $(\mathcal{D} \to \mathcal{D}) \to \mathcal{D}$ is computable.

Proof : Referring back to the proof of Theorem 4.2 and thinking of

$$\mathcal{D} = \{X_n \mid n \in \mathbb{N}\}$$

as effectively given, fix as a relation comes down to

$$\bigcap_{i<q}[X_{n_i}, X_{m_i}] \text{ fix } X_\ell \text{ iff for some finite sequence}$$

$$\Delta = X_{k_0}, \ldots, X_{k_p} = X_\ell,$$

we have, for each $j < p$,

$$\bigcap\{X_{m_i} \mid X_{k_j} \subseteq X_{n_i}\} \subseteq X_{k_{j+1}}.$$

Inside the "for some finite sequence" all the checks are decidable by assumption on D. But the existential quantification of a decidable predicate always gives a recursively enumerable predicate. (And, as there is no implied bound on the size of the finite sequence we are looking for, this really *is* an enumerable set and not generally a recursive set.) □

The major consequence of what we have done up to this point concerns typed λ-calculus. Any expression involving only *effectively given types* and, perhaps, some *basic computable constants* using only the $\lambda, !$-notation defines a computable function of its free variables. And such functions applied to computable arguments give computable values. And such functions have computable least fixed points. Etc., etc. In a definite sense then we have in the "metalanguage", as people say, a quite precise and fully *mathematical programming language* for defining computable operators. It is not a machine implemented language, but it is a mathematically well-defined and easy-to-use language. And when we combine the usual type-definition facility together with *domain equations*, we have an especially powerful language.

/-- **Exercise 7.22j.** `Ssys` -- Scott's positive system generated by singleton
    languages under
concatenation and consistent intersection -- is partially effectively given:
    Definition 7.1
relation (ii) is recursively decidable (`Ssys_cons_computable`, closing C9 / **7.22i(b)
    **).

The name "partially" now undersells the full picture: relation (i) is *also* proven,
    separately,
as `Ssys_interEq_computable` (Exercise 7.22k, `ConsistencyPresentation` was never
    extended with an
`interEq_computable` field to absorb it). Together, `SsysPres` and `
    Ssys_interEq_computable` show
`Ssys` satisfies Definition 7.1 **exactly as Scott states it** -- enumeration, plus
    both relations
recursively decidable -- with nothing deferred. What remains unbuilt is only this
    codebase's
*stronger* `ComputablePresentation` (`Definition71.lean`), which the rest of Lecture
    VII's
formalisation relies on but which is not part of Definition 7.1's text; see the
    section docstring
above. -/

3.8.8 Proposition 7.7 — lists effectively given

PROPOSITION 7.7. For any effectively given domain D, the domain $D^{\S}$ is also effectively given, and all the combinators of Example 6.1 prove to be computable.

Proof: This proof is essentially an exercise, but it is useful to have an easy-to-grasp example. Indeed, to make things easy to reason about, we can assume that D is a system over $\Delta = \mathbf{N}$, and that in the presentation

where

$$D = \{X_n \mid n \in \mathbf{N}\},$$

the relation $k \in X_n$ is *recursive* in k and n. (It is worth thinking why this is so.) Of course, a lot of other things are recursive also.

Now what kind of a system is $D^{\S}$? The construction of 6.1 made it a system over a certain set of strings Γ. For the sake of checking various assertions about computability, we are transposing everything back to $\mathbf{N}$. (These are all denumerable sets in any case.) The set Γ is divided into three equally big parts, and we can do the same for $\mathbf{N}$. Let us write for any $m, k \in \mathbf{N}$ and subset $X \subseteq \mathbf{N}$:

$$mX + k = \{m \cdot n + k \mid n \in X\}.$$

Then by splitting the integers modulo 3 we have:

$$\mathbf{N} = 3\mathbf{N} \cup (3\mathbf{N} + 1) \cup (3\mathbf{N} + 2),$$

and this equation is quite analogous to that for Γ. We then propose this definition for $D^{\S}$:

$$D^{\S} = \{\mathbf{N}\} \cup \{3X \mid X \in D\} \cup \{(3X + 1) \cup (3Y + 2) \mid X, Y \in D^{\S}\},$$

but this does not make the enumeration of $D^{\S}$ all that obvious. This is one way to do it:

$$V_0 = \mathbf{N}\ ;\ V_{2n+1} = 3X_n\ ;\ V_{2n+2} = (3V_{p(n)} + 1) \cup (3V_{q(n)} + 2).$$

Here p and q are the inverse of the pairing functions mentioned in 7.4. They must be chosen so that $p(n) < n$ and $q(n) < n$ for all $n \in \mathbf{N}$. Thus, in calculating V_k where $k = 2n + 2$ we will be using $V_{p(n)}$ and $V_{q(n)}$ where both subscripts are strictly less than k. This observation is required so that $m \in V_k$ is going to be a recursive relation. What we claim is that

$$D^{\S} = \{V_k \mid k \in \mathbf{N}\}.$$

It should be clear that everything on the right belongs to $D^{\S}$. What needs an inductive argument is that everything in $D^{\S}$ is eventually of the form V_k. But this should be fairly obvious owing to the properties of $r : \mathbf{N} \times \mathbf{N} \leftrightarrow \mathbf{N}$.

The reader also has to check that 7.1(i)–(ii) hold for the V_k. The idea is that any such check is either (1) trivial, or (2) something already assumed about D and the X_n, or (3) can be thrown back to some sets V_m with strictly smaller subscripts. Therefore, the checks will give an answer in finite time according to an effective reduction.

Next for the combinators, we have to translate neighbourhood relations into relations among integer indices. A selection of examples must suffice,

$$X_n\ (\lambda x.\, x^{\S})\ V_k \text{ iff } V_{2n+1} \subseteq V_k$$

$$V_m\ \mathrm{proj}_0\ V_k \text{ iff } k = 0 \text{ or } \exists n \in \mathbf{N}.\, m = 2n + 2 \text{ and } V_{p(n)} \subseteq V_k.$$

The reader should write out other cases. □

3.8.9 Example 7.8 — powerset effectively given

EXAMPLE 7.8. We have often made reference to the powerset $P\mathbf{N}$ as a domain and we should check here that it is effectively given. One easy way to see this is to note

$$P\mathbf{N} \cong |T^{\infty}|.$$

The (slight) trouble with $P\mathbf{N}$ is that we usually think of it in terms of *elements* rather than *neighbourhoods*. Going back to Exercise 1.16, we can argue that the neighbourhoods of $P\mathbf{N}$ are ordered not like the finite sets of integers but in the partial ordering *converse* to that. But this is of no trouble, since all will be decidable. What we need first is an enumeration of all finite sets of integers. We can do this by:

$$E_n = \{k \mid \exists i, j.\, i < 2^k \text{ and } n = i + 2^k + j \cdot 2^{k+1}\}.$$

The idea is that $k \in E_n$ means that the exponent k does occur in the binary expansion of n as a sum of powers of 2. All finite subsets of $\mathbf{N}$ are of the form E_n. We then find that as a neighbourhood system

$$(P\mathbf{N}) = \{\mathbf{N} \setminus E_n \mid n \in \mathbf{N}\}.$$

As the relationship $E_n \cup E_m = E_k$ is recursive, there is no trouble in proving that this is a computable presentation. In this system, of course, any two neighbourhoods are consistent. Various combinators on $P\mathbf{N}$ are suggested in Exercise 7.23. □

We end this chapter with an example of another kind of domain construct. This construct is known as the *Smyth Power Domain*. It is defined for any neighbourhood system $\mathcal{D}$ and results in a new system we shall call here $\mathbb{P}\mathcal{D}$. The elements of $\mathbb{P}\mathcal{D}$ behave rather like *sets of elements* of $\mathcal{D}$, but since our elements can be either partial or total, there are certain dangers to pushing the analogy too far. For some purposes a rival construct called the *Plotkin Power Domain* is better, but it leads outside the category of neighbourhood systems as defined in these lectures. Do not confuse $P\mathbf{N}$ with $\mathbb{P}\mathcal{D}$.

3.8.10 Definition 7.9 — power domain

DEFINITION 7.9. Let $\mathcal{D}$ be any neighbourhood system and define

$$\mathbb{P}\mathcal{D} = \left\{ \bigcup_{i<n} (\downarrow X_i) \mid \forall i < n.\, X_i \in \mathcal{D} \right\}.$$

We recall that for any $X \in \mathcal{D}$

$$\downarrow X = \{Y \in \mathcal{D} \mid Y \subseteq X\}.$$

The finite unions in $\mathbb{P}\mathcal{D}$ can be empty (i.e. if $n = 0$). $\square$

Formally, the system $\mathbb{P}\mathcal{D}$ is just more or less the closure of $\mathcal{D}$ under finite unions; however, this would not be an isomorphism-invariant construct unless $\mathcal{D}$ is "prepared". The preparation consists of replacing $\mathcal{D}$ by the isomorphic domain

$$\mathcal{D}^\dagger = \{\downarrow X \mid X \in \mathcal{D}\}.$$

(In this connection refer back to Exercise 1.20.) We remark that

$$\downarrow X \cap \downarrow Y \neq \emptyset \text{ iff } \{X, Y\} \text{ is consistent in } \mathcal{D},$$

and in that case

$$\downarrow X \cap \downarrow Y = \downarrow (X \cap Y).$$

3.8.11 Proposition 7.10 — power domain effective

PROPOSITION 7.10. The power domain $\mathbb{P}\mathcal{D}$ is a neighbourhood system if $\mathcal{D}$ is, and it is effectively given if $\mathcal{D}$ is.

Proof : The system $\mathcal{D}^\dagger$ is a neighbourhood system as we just remarked; indeed it is a positive neighbourhood system. It is easy to prove that the closure of any positive system under finite unions is a neighbourhood system, because the resulting family of sets is closed under *all* finite intersections. (If we left out the empty union, the result would be a positive system.) The proof is obvious since intersection of sets distributes over finite union. So $\mathbb{P}\mathcal{D}$ is a neighbourhood system.

For the second half of the proposition, we just have to constructivize the previous argument. Thus, if

$$\mathcal{D} = \{X_n \mid n \in \mathbb{N}\},$$

then the elements of $\mathbb{P}\mathcal{D}$ can be written as:

$$\bigcup_{i<q} (\downarrow X_{n_i}),$$

and hence are indexed by the finite sequences $\langle n_0, \ldots, n_{q-1}\rangle$ of integers. Now one of the standard devices of recursion theory is to put the finite sequences of integers into a recursive one-one correspondence with the integers themselves. This is the start of the recursive presentation of $\mathbb{P}\mathcal{D}$, since it means we can list effectively all the required neighbourhoods.

Next consider an intersection

$$\bigcup_{i<q} (\downarrow X_{n_i}) \cap \bigcup_{j<r} (\downarrow X_{m_j}) = \bigcup_{\substack{i<q \\ j<r}} \downarrow (X_{n_i} \cap X_{m_j})\,.$$

Some of the terms which are $\emptyset$ have to be thrown out — but this requires only a finite number of decisions all computable by assumption. Now we have to rewrite

$$X_{n_i} \cap X_{m_j} = X_{k_{ij}}\,,$$

but the finding of k_{ij} is also computable. *Finally*, we have to re-order the doubly indexed sequence into a singly indexed sequence of length $q \cdot r$, but this is easily seen to be computable also. Therefore, intersections can be "calculated".

It remains to be shown that equality between neighbourhoods in $\mathbb{P}\mathcal{D}$ is decidable. The question really comes down to deciding something like:

$$\downarrow X_k \subseteq \bigcup_{i<q} \downarrow X_{n_i} .$$

Now since $X_k \in \downarrow X_k$, we find that the above is just equivalent to:

$$\exists i < q.\, X_k \subseteq X_{n_i} .$$

By our assumptions on $\mathcal{D}$, this is decidable. (It is this part of the argument that required the passage to $\mathcal{D}^\dagger$. It does not seem to be generally true that the closure under finite unions of an effectively given system is again effectively given.) □

One of the main reasons that $\mathbb{P}\mathcal{D}$ is like a power domain is the possibility of forming "finite sets".

3.8.12 Definition 7.11 — finite sets of elements

DEFINITION 7.11. For elements $x_0, \ldots, x_{n-1} \in |D|$ we define

$$\{x_0, \ldots, x_{n-1}\} = \{z \in \mathbb{P}D \mid \exists X_0 \in x_0 \ldots \exists X_{n-1} \in x_{n-1}.\ \bigcup_{i<n} (\uparrow X_i) \subseteq z\}.$$

(Note, we could also write $\forall i < n.\ X_i \in z$.) □

3.8.13 Proposition 7.12 — finite sets are approximable

PROPOSITION 7.12. The mapping

$$\lambda x_0, \ldots, x_{n-1}. \{x_0, \ldots, x_{n-1}\} : D^n \to \mathbb{P}D$$

is approximable and is computable if D is effectively given. Moreover, the map $\lambda x. \{x\}$ shows that $D \trianglelefteq \mathbb{P}D$, and we also have the law:

$$\{x_0, \ldots, x_{n-1}\} = \{x_0\} \cap \cdots \cap \{x_{n-1}\}$$

as an intersection of filters.

Proof : The second part shows that everything reduces to $\lambda x. \{x\}$. We see that

$$X_k \ (\lambda x. \{x\}) \bigcup_{i<q} (\uparrow X_{n_i}) \text{ iff } \exists i < q. X_k \sqsubseteq X_{n_i}.$$

Thus, $\lambda x. \{x\}$ is an approximable mapping and is computable in the effectively given case.

The proof of the law can be reduced to the special case

$$\{x\} \cap \{y\} = \{x, y\}$$

for the sake of illustration. In terms of finite elements of the two domains D and $\mathbb{P}D$ we find

$$\{\uparrow X\} = \uparrow\uparrow X,$$

and so,

$$\begin{aligned} \{\uparrow X\} \cap \{\uparrow Y\} &= \uparrow\uparrow X \cap \uparrow\uparrow Y \\ &= \uparrow (\uparrow X \cup \uparrow Y) \\ &= \{\uparrow X, \uparrow Y\}. \end{aligned}$$

An equation between approximable functions that checks for finite elements also holds for all elements.

Finally, we note that

$$D \cong D^\dagger \trianglelefteq \mathbb{P}D$$

and that the isomorphism involved is just $\lambda x. \{x\}$ by what we saw on the finite elements. □

Further combinators on the power domain are given in the exercises.

EXERCISES

3.8.15 Exercise 7.13 — axiomatic neighbourhood structure

Show that an effectively given domain can always be identified with a relation $\mathrm{INCL}(n, m)$ on integers, where the two derived relations

$$\mathrm{CONS}(n, m) \text{ iff } \exists k.\, \mathrm{INCL}(k, n) \text{ and } \mathrm{INCL}(k, m);$$

$$\mathrm{MEET}(n, m, k) \text{ iff } \forall j\, [\mathrm{INCL}(j, k) \text{ iff } \mathrm{INCL}(j, n) \text{ and } \mathrm{INCL}(j, m)]$$

are both recursively decidable, and where the following axioms hold:

(i) $\forall n.\, \mathrm{INCL}(n, n)$;

(ii) $\forall n, m, k.\, \mathrm{INCL}(n, m)$ and $\mathrm{INCL}(m, k)$ imply $\mathrm{INCL}(n, k)$;

(iii) $\exists m\, \forall n.\, \mathrm{INCL}(n, m)$

(iv) $\forall n, m.\, \mathrm{CONS}(n, m)$ implies $\exists k.\, \mathrm{MEET}(n, m, k)$.

(Hint: Consider the neighbourhood system

$$\mathcal{D} = \big\{\{m \in \mathbf{N} \mid \mathrm{INCL}(m, n)\} \mid n \in \mathbf{N}\big\}.$$

Is this essentially any effectively given system?)

/- concordance: source L4609 EXERCISE 7.13 axiomatic neighbourhood structure -/
/-- **Exercise 7.13 -- the abstract data.** A relation `INCL : Nat  ->  Nat  ->  Prop`
    together with the
witnesses and decidability/axiom data Scott requires. The derived relations are
`CONS`/`MEET` (below); the literal existential axioms (iii)/(iv) are `axiom_iii`/`
    axiom_iv`.

We carry `topIdx` (a master code) and a primitive-recursive `meetIdx` as *data* --
    exactly mirroring
`ComputablePresentation`, which carries its `inter` function as primitive-recursive
    data rather than
recovering it by an unbounded search. This is the faithful "effective" reading of
    axioms (iii)/(iv).

3.8.16 Exercise 7.14 — primitive recursive witnesses

(For recursive-function theorists.) Prove the statements after definition 7.2 about the existence of primitive recursive functions for showing things recursively enumerable. (Recall that a non-empty set is r.e. iff it is the range of a primitive recursive function.) Show also that every computable element $y \in |E|$ can be written

$$y = \bigcup \{\uparrow Y_{t(i)} \mid i \in \mathbf{N}\},$$

where $t : \mathbf{N} \to \mathbf{N}$ is primitive recursive and where we may assume $Y_{t(i+1)} \subseteq Y_{t(i)}$ for all $i \in \mathbf{N}$.

/-- **A non-empty recursively enumerable set is the range of a primitive recursive
    function.** This
is the precise content of Scott's prose after Definition 7.2 (*"there is a primitive
    recursive `r`
with `y = {Y_{r(i)}}`"*). Given a witness `a  in  p` and the `{0,1}` decider `qc` of
    the relation `q`
underlying `p` (`p n  <->  exists  i, q <i,n>`), the function `r w := selectFn (isOne (
    qc w)) w.2 a` enumerates
`p`: on a code `w = <i,n>` with `q <i,n>` it returns `n`, otherwise it returns the
    fixed `a`. Its
range is exactly `p` (the fall-back `a` covers the codes that do not witness anything
    -- this is where
non-emptiness is used). -/
theorem repred_exists_primrec_range {p : Nat  ->  Prop} (hp : REPred p) {a : Nat} (ha

/-- **Exercise 7.14, Half 2 (Scott 1981, PRG-19).** Every computable element `y  in
    |?|` can be
written `y = ? {Y_{t(i)} ? i  in  Nat}` with `t : Nat  ->  Nat` primitive recursive and
     the approximations
*decreasing*, `Y_{t(i+1)}  subseteq  Y_{t(i)}`.

The index set `{m ? Y?  in  y}` is r.e. (`ComputableElement`) and non-empty (it
    contains the master
`Delta`, by `y.master_mem`), so Half 1's `repred_exists_primrec_range` lists it as the
    range of a
primitive recursive `r_0`. Running intersections (`tFun Q r_0`) turn this into a
    decreasing chain whose
members are still in `y` (a filter is closed under ` I `) and still cofinal in `y` (
    each
`Y_{t(i)}  subseteq  Y_{r_0(i)}`), so the principal-filter union is unchanged. -/

3.8.18 Exercise 7.16 — curry as an enumeration

Let $D_0 = \{X_n \mid n \in \mathbf{N}\}$, $D_1 = \{Y_m \mid m \in \mathbf{N}\}$ and $D_2 = \{Z_k \mid k \in \mathbf{N}\}$ be three effectively given domains. Complete the proof of 7.5 by writing out curry as a relation between neighbourhoods. Is it a recursive set or only a recursively enumerable set?

/- concordance: source L4645 EXERCISE 7.16 curry as an enumeration -/
/-- **Exercise 7.16 -- `curry` is a *recursive* set.** Relative to the function-space
    presentations
`PA` of `(?_0 x ?_1 -> ?_2)` and `PB` of `(?_0 -> (?_1 -> ?_2))` (and the inner one `Pc`
     of `(?_1 -> ?_2)`) built by
Theorem 7.5, the `curry` combinator's neighbourhood relation is **recursively decidable
    **:

  `Xenum_PA n curryComb Xenum_PB m  ?  gNb m = 1  ->  forall  e  in  ?m?, gNc e_2 = 1
    ->
                                          forall  e'  in  ?e_2?, X_PA n  subseteq
    X_PA (curryStepCode e_1 e')`,

a bounded double-`forall ` over the coded entry-lists of the recursively *decidable*
    function-space
inclusion. So `curry` is a recursive set -- exactly as for `eval`. -/

/-- **Exercise 7.16 -- `curry` is computable, and in fact a recursive set.** If `?_0, ?
    _1, ?_2` are
effectively given, then there are computable presentations of `(?_0 x ?_1 -> ?_2)` and
    `(?_0 -> (?_1 -> ?_2))`
relative to which the `curry` combinator's neighbourhood relation is **recursively
    decidable**
(`RecDecidable_2`) -- hence `curry` is a computable map (`ComputableMap`, the r.e.
    condition of
Definition 7.2). The answer to Scott's question: `curry` is a *recursive* set, not
    merely r.e. -/

3.8.19 Exercise 7.17 — recursion over lists

Complete the proof of 7.7 for showing that $D^{\S}$ is effectively given if D is. Include all the combinators of 6.2. Prove also that if E is effectively given and $u : D \to E$ and $v : E \times E \to E$ are computable, then the unique strict mapping $g : D^{\S} \to E$, where, for $x \in |D|$ and $y, z \in |E|$,

$$g(\mathrm{in}(x)) = u(x), \quad \text{and}$$

$$g(\mathrm{pair}(y, z)) = v(g(y), g(z)),$$

is a computable mapping.

/-- **Exercise 7.17 (Part 2) (Scott 1981, PRG-19).** If `E` is effectively given (
    presentation `Q`) and
`u : D  ->  E`, `v : E  x  E  ->  E` are computable, then the unique strict
    catamorphism `g : D^S  ->  E`
(`gMap`) is computable.

The index relation `X_n g Y? = GRel u v (V_n)(Y?)` is realised as the recursively-
    enumerable existential
`exists  cert, gEval<n,cert>.ok = 1  /\  Y_{cert.out} = Y?` over the primitive-
    recursive certificate evaluator
`gEval`. Soundness (`gEval_sound`) and completeness (`gEval_complete`) of the
    certificate give the
equivalence; the deciders `fe`/`fU`/`fV` are read off `Q.eq_computable` and the r.e.
    relations of
`u`/`v`. -/

3.8.20 Exercise 7.18 — effective isomorphism

Two effectively given systems D and E are *effectively isomorphic* iff … (complete the sentence!). Show that if D is effectively given then the isomorphism

$$D^\infty \cong (D^\infty)^\infty$$

is effective.

3.8.21 Exercise 7.19 — power domain functor

Prove that $D \mapsto \mathbb{P}D$ is a functor by defining for each $f : D \to E$ a mapping

$$\mathbb{P}f : \mathbb{P}D \to \mathbb{P}E$$

by the formula

$$\bigcup_{i<n} \downarrow X_i \quad \mathbb{P}f \quad \bigcup_{j<m} \downarrow Y_j \quad \text{iff} \quad \forall i < n \exists j < m.\, X_i f Y_j\,.$$

Be sure to check that $\mathbb{P}f$ is approximable and that $\mathbb{P}$ preserves identity maps and composition. If f is computable, is $\mathbb{P}f$? Is there a combinator $\lambda f.\, \mathbb{P}f$? What is

$$\mathbb{P}f(\{x, y\}) = ??$$
